are not talking about gobs of power in any case.

DDS vfo's have very low phase noise, and the ones that can be clocked
at 100mhz or higher can deliver quite low spurs. The AD9954 series
have a 14 bit DAC and can make a very good HFO for a single conversion
receiver with no PLL loop filter needed to clean up the output.

Why not just say Watts or milliwatts and be done with it?
Why drag dB into it?

BTW dB means deci-bell, why not use a WHOLE BELL.
(and the brass figligee with bronze oak-leaf palm to anybody
who can guess who this unit of measure was named after!)

Maybe because dB gives you a better idea of the limited communications benefit to be achieved by turning up the power?

It also simplifies factoring in antenna gain, feadline loss, etc...

Really this is same idea as using a sliderule - take the log of everything and then gain/loss becomes simple addition subtraction.

One downside though is that when playing around with a signal generator calibrated in dB, you can fail to appreciate the degree to which you may be turning up the power to something under test, at least until you get used to the numbers.

1590. Looking for a GPS disciplined frequency synthesizer

I am looking for a freqency synthesizer in the band 100Mhz-1Ghz very
stable to test quipments over a long period.

I heard that now there are some who are GPS disciplined?
How does it work ?
Which is one do you recommend ?

Phil.

...a long explanation, but a needed one.
One of the most important characteristics of a mixer is its ability to handle large input signals without overloading. if overloaded by an unwanted signal, chances are that it will not be able to handle the weak signal you're interested in. the physical mechanism involved is not important, except for the fact that increasing current through an active mixer (re FET or transistor, or the injection power in a DBM tend to alleviate the problem in some measure. the nois figure of both is more or less equal and adequate in the HF range. the main advantage of the dual gate MOSFET is that it needs much less power from the local oscillator and can save you an amplifying stage. Not really crushing, but sometimes neeedful.
If you're talking about a simple first receive I'd go with the MOSFET mixer. there are very good examples in the hand book. iI used them for years with success and still using them in one form or another.
the problem is much less severe at the second mixer, because the IF filters tend to defend it from large unwanted signals and the amplituse variations are also smaller due to AGC action.
Soooo , KISS (keep it simple, stupid!!!), a very good adage. goood luck with your first.

Before you get too far into spending money, you have to decide what stability and sidebands/phase noise you can deal with. Also, if you need traceability you have to start with that in your spec.

You can easily sink $500K into a fancy new synthesizer and end up with something that's not good enough for a lot of truly stringent applications.

Alternatively a surplus Z3801A (a few hundred $) + a surplus HP synth (a few hundred $ more) chained to the Z3801A's 10MHz out might do what you need.

The GPS lock gets you to the part per billion in precision. If the few PPM level is good enough you might not need GPS, the OCXO or TCXO that are typically built into the synths of the 80's and 90's may be good enough with a little calibration check-up.

Tim.

Hi

If you think the situation in short waves today:
Russian and their previous satellite country jammers are quiet
Local broadcast is nearly completely in FM
Propaganda is no more effective to transmit in short waves
Commercial data is practically in Internet. and in satellites
Marine communication is in satellites.

All this means less cross modulation products in first mixer than some
sixteen years ago
Atmospheric noise in sw is much higher than the noise of modern front
and mixer stage
Advantage of diode mixer is marginal
IGFET mixer is simple and advanced solution for DIY project.
IGFET mixer doesn't need any front amplifier stage.
A selective band filter in front of mixer is superior to broadband
transformers
I am using loosely coupled 3 stage band filter tuned by variable triplet
air capacitor
3 coils for low end of sw and 3 coils for upper end of sw.
Coils are DC selected by small reed relays
KISS

If you are constructing premixer then I recommend DBM to keep birdies
in low levell
For IF/BFO my recommendation is also DBM or "semi DBM"
For both of those DBM solutions I recommend you to Google a nice
advanced component MC1496.
In some Motorola handbooks and ARRL handbooks are examples for MC1496 as

DBM, product detector and balanced modulator.
It is mostly used in single ended circuits in RF meaning and balanced
for DC

Actually I believe the unit is a Bel. Yes 10 dB is one Bel. For some
reason nobody uses the bel...or for that matter the milibel, microbel,
kilobel or megabel... Decibels are just about right all the time.
Perhaps it is because no one knows for whom it tolls...

Perhaps "no one knows for whom the decibel decides." (:-)

Also, we Engineers love to talk in dB... You can just add and subtract
them...

Then there is the practical aspects. If you have 0.1 watts going into an
step attenuator set to 32dB, how much is coming out? However, starting with
20dBm into this attenuator yields an easy -12dBm.
You get used to it, just like you got used to power in watts.

73, Steve, K9DCI

PS: dBm is dB _relative to_ (not over) one mw. (-123 dBm is "under" a mw)

Sam-

What frequency is this repeater on? A sensitivity of 0.8 uV doesn't sound very good to me. On 146 MHz I'd expect that without any external preamp, although it might be good at 1200 MHz???

There's a good discussion about the advantages and disadvantages of various mixer types, for different applications, in "Experimental Methods in Radio Frequency Design", a book I strongly recommend.

As others have pointed out, there's no one right solution. Even for use in what seems like a simple, constant application (e.g. a CW receiver for the 40-meter band), the choice of which is more appropriate can swing one way or the other based on how you intend to use the receiver.

As one example given in EMiRFD, if you're looking for a simple receiver which is intended for QRP operation on backpacking trips, then the low power consumption, and the mixer gain of an active mixer such as a Gilbert cell (e.g. SA602 and similar) can make this the ideal. Out in the woods, the RF levels will be low, and the relatively low IP3 of these sorts of mixers isn't likely to be a problem.

On the other hand, if you're planning to build a receiver which may have to operate in a strong-adjacent-signal environment (e.g. for Field Day or other contesting), then you may want to favor a diode-ring double-balanced mixer operating at a high LO-injection level, and the devil take the power consumption :-)

The FET-switch mixers seem to be a really nice alternative, and although they've gotten relatively little visibility in amateur-radio applications they've become very popular in commercial use (e.g. cell-phone handsets). I haven't yet had a chance to play with these myself but they look like fun!

That's not my code, I should (hastily) note -- it's a comment that
reflects the fact that the Win32 GetFileTime() API returns the number
of 100-ns intervals since 1-Jan-1601, and I multiply the result by 10
to obtain a 64-bit microsecond counter. I'd assume that MS is doing
the right thing.

If you really intend to use mixers with such horrible IP3 figures, I would suggest using a very selective front end ahead of it. For a single band CW receiver some fixed tuned stages might suffice, but otherwise some tunable input filters should be used.

In Europe, there are several high power broadcasters starting at 7100 kHz, which would easily overload the 40 m receiver. Assuming loaded Q of 100 and the front end tuned to 7000 kHz, the -3 dB bandwidth would be +/-35 kHz from the centre frequency with some usable attenuation at 7100 kHz.

Using fixed tuned octave wide front end filters with the 602 is just asking for trouble.

Source record: 13306

There have been recent discussions about the interchangeability of coaxial plugs and sockets, their dimensions and their impedances. But, as usual, the magnitude of the electrical effects is never mentioned. Without numbers nobody knows what they are talking about.

A coaxial connector is a very short length of transmission line but at UHF and microwave frequencies it is an appreciable fraction of a wavelength. When 1/4-wavelength long it has the property of transforming a mismatched termination to another value. When 1/2-wavelength long the input impedance repeats the value of the termination. The SWR on an adjacent line is a function of the input impedance.

What is the effect of using a 75-ohm coaxial connector in a 50-ohm system?

What is the effect of using a length of transmission line of 50-ohms nominal impedance when it is actually 53 ohms?

With mixed values of line Zo at what high frequency does the SWR and reflection loss become excessive?

Program CONNECT.exe calculates the effect of inserting a length of line in a system of different Zo. Differences can be large or small. Line length can be physically very short.

For a given frequency, mismatched Zo's and a velocity factor, input impedance, SWR, reflection coefficient and reflection loss are calculated. (Reflection loss is sometime known as mismatch loss).

The program is worded in terms of a connector mismatch but has other applications.

Input data can be varied in small increments from the keyboard while observing the effects on calculated values. Download CONNECT from website below. It has entertainment, educationaal and practical value. Amuse yourselves!

OH2BT's comments about how much better things have gotten in Europe really made me say hmmmm.... I only recently heard actual measurements, rather than whining, and things are pretty horrible today - they must have been intolerable decades ago.

Tight front ends and careful control of levels obviously are important with any mixer, but especially something with the gain of a 602. Nevertheless, I doubt there are many cases where a 602 would be even useable in Europe, let alone "good".

Since they are low order odd harmonics, is a PLL even necessary, or could a square wave sort of buffer, a filter at the desired frequency and then an amplifier tuned there do the trick?

With a PLL, you will still need to switch components for each frequency range - generally you get less than an octave (factor of two in frequency) out of a single VCO, but changing the inductor and/or fixed capacitors for each band shouldn't be too hard.

We had problems keeping Radio Moscow out of _audio_ equipment :-).

Guitar amplifiers were quite problematic with long cables and a top
capacitance (the guitar and the player) at the end, bringing quite
large RF voltages into the audio stages, causing rectification in
unfiltered input stages.

Certainly usable for receiving strong international broadcasters, in
which case the input signals can be sufficiently attenuated, however,
trying to receive any weak signals with such an attenuator at the
front end, is not very productive :-)

This may interest some.
I believe, although can't find the actual reference now, that the decibel
was used rather than the bel from the start because the numbers were very
close to those of the m.s.c. used before it.
The following are from "Signal Training" Vol 2, Part 3 (Line telephony and
Telegraphy) 1936, HMSO, an Army training manual:-

" The decibel.- The standard unit for measurement of telephone transmission
in this country [UK] is now the decibel, which is one-tenth of a bel, and
has superseded the mile of standard cable."

and

"1 decibel = 1.084 m.s.c. = 1.151 decineper"
"1 m.s.c. = 0.9221 decibel = 1.0616 necineper"

and just to explain the decineper

"In the majority of European countries the unit of measurement for telephone
transmission is the decineper, which is one-tenth of one Neper. The unit is
named after Napier, the originator of Naperian or natural logarithms, i.e.
logarithms to the base e. The neper is a measurement of the total
attenuation and can be defined as the natural logarithm of the ratio of the
currents at two different points in a network or apparatus, or as half the
natural logarithm of the ratio of powers at two different points in a
network or apparatus."

The book doesn't show an upper case B for Bel in db so that must have come
later but it does use the plural as in "30dbs" so should we be using dbuVs
etc? I've used an artificial cable box for 75 ohm video but have never seen
a reference m.s.c., originally an actual lump of cable but later a series of
switched networks.

Message-ID: <du9b5l$b2j$1@nwrdmz02.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 13312

I think that basically is the problem.

Because the impedance is not set up properly on the cavities (the pass plunger is a little off the correct impedance), then the preamp is operating with a non-optimal impedance.

Desensing the preamp reduces the gain so reduces the amount of noise the preamp is generating.

Sounds like a little lesson well learnt to me. Now on to returning the cavities up properly.....;

Thanks all,

Sam

Or very nearly so.

As it's Friday afternoon, I'm sure the Complete Buffoon (CB) who seems to speak Copious Bowlocks (CB) when it comes to matters scientific, will be along soon with his Chattering Balderdash (CB), in which he might explain a previous posting maintaining that electrons 'whizz about'.

On the other hand, he just might carry on ranting about the Copper's Boot (CB) and trying to make a Casus Bellum (CB) out of it. After all, Cui Bono (CB), as one might ask?

Cheery Bye (CB).

Quite, - there is some wobble and skin effect.

With DC there is movement in one direction however the speed is in the
orders of inches per hour so that's pretty much nil too IMHO ;-)

I discovered that the solder connections on a capacitor were bad.
Apparently, the solder iron overheated the contacts on the board
causing plastic on the board to melt onto the contact. I made a
temporary fix by soldering the capacitor directly to the resistors it
is connecting. I'm picking up radio stations now, but there is a loud
squeal. Maybe the timer is oscillating? Is there anything that can
clean melted plastic off a contact?

1615. Radio Hammery - The Weekly FAQ

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-03 15:44:32 UTC
From: Plod's Conscience <radio.ham@lycos.co.uk>

What is Ham Radio?

It is becoming increasingly difficult to fly the flag for
decency and for civilised behaviour in Radio Hammery. Even
the Usenet newsgroups dedicated to the cause have degenerated
into a hotbed of abusive onslaughts by those who ought to know better.
However, there still exists the fundamental basis on which Ham
Radio is based, and that will never die. This FAQ ("What Is
Ham Radio?") will be regularly published and will not be
shouted or bullied down. It is important that those of a
technical bent, who are the natural seed-corn of Radio Hammery
and who gravitate towards us to be the real novitiate, can
still find us, (and know that we are still here), their fellows.

-----ooooo-----

Please remember that this FAQ is a _POSITIVE EXHORTATION_
to you to exert yourselves to join our fraternity! (If you find
otherwise, then perhaps you are already classing yourself in the
mediocre groups of those who are criticised in the FAQ and from
whom we _MUST_ dissociate? If so - it's never too late for
a re-taxonomisation on your part - there's nothing elitist about
us, and we welcome all those who are prepared to put themselves
out in order to join our ranks!)

-----ooooo-----
So,.....What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one

else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

I think the board has some kind of plastic or polymer coating because the heat from the solder iron causes the clear coating to melt. I'll hook the circuit up to an o-scope to see what part is oscillating. I suspect something is miswired, I'll let you guys know later in the week how it went. Thanks for everyone's help!

He is... that's why he probably does a cut and paste posting the same stuff
every weekend rather than post anything interesting. One is also beginning
to think either that or he has a newsgroup bot automatically posting his
mail for him and set for the weekend.

Some doctors recommend a moderate amount of alcohol to reduce high blood pressure. Make it red wine and you can reduce your cholesterol at the same time ;-)

Of course, too much alcohol isn't a good thing, it can lead to long term brain damage and all sorts of mental problems.

1630. Permeability of steel filled epoxy?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-03 22:40:52 UTC
From: cs_posting@hotmail.com
Message-ID: <1141425652.682734.94300@e56g2000cwe.googlegroups.com>
Source record: 13331

Anyone have a guess as to the permeability of steel filled epoxy?

Was sort of wondering what would happen if one tried to make RF inductor or transformer (torroid, etc) cores out of the stuff...

with care, it can even reproduce threads, so tuneable slugs might be possible.

It's available as putty in tube form in many hardware stores, and as a castable liquid from industrial supply catalogs - though obviously if ordering something from a non-local supplier, it might as well be a proper core from Amidon.

(and yes, I may go ahead and try it... soon as I get my workbench set back up to the point where I could build something to measure the results)

My guess (based on my attempts to make cores out of granulated ferrite
and epoxy) is that you will be doing well if you achieve a relative
permeability higher than 10. And that assumes that the iron is pure,
iron, or silicon iron, not steel.

There was an article in the ARRL HB (1995 and probably others)
about using an SD5000 quad mosfet as a mixer. I bought a few
of these transistors a few years ago (now where did I put them,
got lost in the last move!). They are supposed to make
a very good mixer. The only disadvantage was the circuit
required injection at twice the lo frequency as it used a jk flip
flop to develop the required 180 degree injection. I suppose
a balum could do the same thing. In any case the AD9954 DDS I am
thinking of using can clock to 400mhz and develop output to
160mhz, so getting up to 80mhz (for use with a 9mhz if) would still
be no problem.

I would expect that you would have problems with loss due to hysteresis
in the steel. A good big pile of rust may be better.

I wonder: if you had your Jr. Experimenter's Chemistry set and a pile of
iron filings, what would make the best core material?

Air (or epoxy -- doesn't matter as long as the relative permeability is 1) gaps between the particles will have a much greater impact on the characteristics than the steel itself. Compared to the steel itself, the material will have much lower permeability, much higher saturation flux density, and much lower hysteresis. I'll bet the repeatability will be pretty awful.

Also see N6NWP's article from QST June 1993. And the
H-mode mixer by G3SBI in RadCom and various other RSGB
publications.

> I bought a few of these transistors a few years ago...
I see the SD5000 is still listed on Calogic's website
http://www.calogic.net/html/dmos.html Is the SD5000
still widely available? The search engines turn up a
lot of data but very few suppliers. Perhaps a ring of
discrete MOSFETs or a fast switch IC like the FST3125
might be a better choice.

Hi !

At the same time Signetics included to the same fet family a double fet
SD6000
It was planned for front end applications
Single fets were done under type numbers SD305 and SD306
All three were N-channel enhancement types. Positive bias only.
I wonder whether Signetics still exists. Signetics was bought by Philips
company.

I use those fets successfully in one of my conventional type homebrew
tranceivers.
The first if is having a 10.7 MHz xtal filter. That is mixed down to
455 kHz either with 10.245 MHz or 11.155 MHz xtal
Sideband selection is done with the selection of mixing direction.
455 kHz is using Collins mechanical filter having very good shape factor
and special skirt for lower sideband use.

GM Ed. Certainly a better choice when it comes to conversion loss. I've built a half dozen SD5000 mixers and although at least one of them managed a measured +50 dBm Ip3, (G3SBI measured it not me!) I never managed to get the conversion loss below 9 dB and more often 10. Conversely, the 3125/ family readily does 4.8 dB conversion loss thanks to the very respectable Rds on. REALLY simplifies things in the front end department, to at least 30 MHz, with attention paid to the front end filters, you can get away without an RF amplifier.

1640. Biasing amps for linear service -- design question

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-04 18:03:54 UTC
From: bill.meara@gmail.com
Message-ID: <1141495434.077634.71180@p10g2000cwp.googlegroups.com>
Source record: 13341

I've been looking at simple circuits used to bias solid state, common emitter, BJT amps for linear service. A very common technique is to use the voltage drop (.7 V) across a forward biased diode to bias the base of the final. See EMRFD page 2.37.

But when you do this, don't you end up with a very, very low emitter voltage (whatever you have on the base minus the drop across the base-emitter junction)? With a voltage divider bias network you can arrange to have several volts on the base, a couple of volts on the emitter, and then use the emitter resistor to set the Idc. But using the diode scheme, you just don't have much voltage on the emitter to play with.

Am I missing something here?

Doug DeMaw has a 1 watt linear amp in the Feb 1997 issue of CQ that uses this circuit. In this circuit he has 7 ohms between the emitter and ground. I measure .022Von the emitter -- that would yield an Idc of only 2 milliamps.

DeMaw also discusses this biasing arrangement on page 128 of his QRP Notebook.

Is the answer that we are biasing for Class AB and not class A and the higher level of Idc is not needed? Also, in most of these circuits, they the emitters are connected directly to ground -- that would definitely increase Idc.

For a power amplifier a low emitter voltage is the point -- any voltage that you use up biasing the emitter is voltage that isn't available for generating RF power. So you bend over backwards to have low or no emitter resistance. You'll note that the diode-based bias supplies require that the diode is in thermal contact with the transistor cases -- this is to keep the diode's forward drop close to the required

base-emitter drop.

In the DeMaw circuit he is almost certainly biasing for class AB, for higher efficiency, and using the emitter degeneration for linearity (the article should say -- DeMaw was usually good about telling you what he was about).

I have seen 3-500Z tubes mounted in the johnson ceramic sockets. The Heath SB-220 uses them.
Will the 4-400 tube handle the airflow the same way? Usually you see the air system sockets used so that the air will flow up through the bottom. Will the filament connections remain solid in a 275 ceramic socket with a muffin fan blowing across the tube?
? I have seen the sockets raised a bit so that the filaments get cooling. Just wondering if the 4-400 would work that way as well? Any experience with this?

Every year, Shelly the tortoise gets lost or manages to escape the garden. It can take days to find her. I would like to build a locating device so that I can track her down.
The basic requirements are:

a) that the 'transmitter (transponder?) on the tortoise is as small as possible.

b) that it can be made by an electronics numpty. I have basic soldering skills, and can eventually work out a circuit diagram.

Can anyone point me in the right direction?

TIA
Floatything (an escapee from uk.rec.sailing)

Use a blob of epoxy resin with a long string stuck in it and tie it to a post! Either that or glue a mobile to it and call each night - you should hear the ringtone. You can already get small tracking devices if you look on a search engine such as GOOGLE.
I didn't think people still had tortoise! They go for between £400 and £500 in the UK depending on the seller and people in some countries eat the poor things. They turn them upside down and cut the insides out. Quite revolting.

==========
During the late 1970s ,the old 405 lines TV system in the UK operating
in Band 1 (approx 45 -65 MHz) was decommissioned and some equipment
landed at junk sales held at radio clubs . I managed to obtain two 1 kW
amplifier racks (out of 7 released from a local 7 kW TV repeater)

The rack had 2 QY4-400 (tetrode)valves with the (flat,ceramic) sockets
fitted approx 12 mm below the chassis on stand-offs . The space under
the chassis was fully enclosed (almost air -tight) and was fitted with a
pressure switch (with a large diaphragm to sense and switch a low pressure).
A centrigugal fan blew air under the chassis which escaped via the valve
socket openings thus cooling the valves. There were no valve 'chimneys'

Upon fan failure the pressure switch would initiate the rack's shutdown.

A simple but effective way of cooling the valves.

~~~~~~
A fun project, but I'd recommend a different tube. The 6J6 was
notorious for intermittents. It was a bad design from the start. In my
other life as a TV repair guy, I changed hundreds of them.

Doug, Here's what I remember from several RCA and Collins Broadcast transmitters and a KW amp I built: Those ceramic sockets SHOULD have holes in them of about 1/2" diameter. Line up a 4-400A with the socket. Notice that the BASE of the 4-400A has holes that line up with the socket holes. Notice that the 4-400A has a metal base which has a series of holes around it. It's very important to put lots of air thru those holes to flow around the tube base pins. If you're going to run lots of dissipation (definite color on plate) then the usual approach is to mount the socket just below the chassis on standoffs or about 3/16 to 1/4" as I recall. THe SIZE of the hole in the chassis then is set to have about 3/16 to 1/4" of space around the outside of the metal tube base, so there is additional airflow which will hopefully stay fairly laminar around the upper part of the tube envelope. NOTE: Normally that metal base ring is grounded by several metal clips.

SOME systems used the "Air System Chimney" (A pyrex glass open-topped "bottle" around the tube) to direct the air around the tube envelope, although 1000W OUT Broadcast transmitters from Collins and RCA did not use them, and their high level modulators put out 750 watts of audio, at, say, 50 percent efficiency, so there was about 375 watts of plate dissipation per 4-400A at 100% sinewave modulation. Which at one time was OK, because the actual duty cycle on "Typical Program Material" was much lower. But about 1970, as I recall, watching the plate color during "Magic Carpet Ride" by Steppenwolf, with an asymetrical limiter, 20 db of syllable-rate compression, plus the pre-processing of the airplay cart by a demented Program Director, the plates looked a lot like 100% modulation during an Audio Proof of Performance test :-)

For Coherent CW - go to http://www.google.com/
Type in Coherent CW -- gets lots of articles

Quick bottom line
Coherent CW is morse code with precise timing and frequency accuracy, so you can use 20Hz filters and integrators to get remarkable results from very weak signals.

They come off the same production line, but one has been tested over a
wider temperature range. Generally the looser specced parts from any
semiconductor vendor are either untested at the tighter spec (and may
work there) or are rejects from the tighter spec testing but still pass
lower spec.

If you aren't going to operate where you are either shivering or baking
then the looser spec part will be fine.

The NE602 was an old part. The product was bought by another company (Signetics?) who renamed it SA602, but kept the rights to the name NE602 so sometimes you still find an NE602. Worse yet, the NE/SA 612 is a little more widely available and somewhat cheaper -- sometimes a lot cheaper. It is the same part with a little different set of QC tests, so for any imaginable application, all 4 parts are the same thing. If you were doing some military application there might be a slight advantage to the 602 over the 612, but even that isn't clear from the spec sheets. Usually (but not always) if you find an NE part it will be "old stock". Sometimes the 602 will be a few cents more than a 612, other times it will be 2 or 3 times the price, although it's only a couple buck part so paying double isn't going to break the bank, anyway.

The NE602 was widely used in a lot of projects, and still is. Hams got used to calling it an NE602 so the name stuck, even though an actual NE602 is hard to find anymore and the alternatives at least as good. Guys who build lots of receivers have a drawer marked NE602 that probably contains more SA612's than NE602's.

Anyone have ideas or sources for remotely monitoring an infrequently used car's 12V battery to make sure it didn't go dead from simple attrition?

Ideally, I want some sort of contact closure when voltage drops below a certain point. I want to sent that information wirelessly to a base unit inside the house that would flash, beep, and then call my cellphone and say "Dad's wheelchair van needs recharging."

What I would like to do is hijack a wireless thermometer - the thermistor probe should be able to read voltage with a few modifications to the probe end. The thermometer base station has an "alarm on temperature" feature that could, with a little recalibration, serve to monitor dropping voltage and to beep when it dropped below a threshold I would set. With any luck, I could get it to read 100 degrees when the battery was fully charged and 0 degrees when depleted. Not sure there would be linearity along the scale, though! <g>

Another thought would be some sort of docking cradle on the front bumper that allowed feeding a charging current to the car without the need for connecting charging cables or a charger that can be dragged down the street for several blocks until the car manages to run over it (the reason why I just don't leave the sucker plugged in all the time for him!).

1670. Picket-fenced ground gias next to microstrip traces

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-07 17:19:40 UTC
From: Joel Kolstad <JKolstad71HatesSpam@yahoo.com>
Message-ID: <120rg6otjsdv574@corp.supernews.com>
Source record: 13271

I've noticed that various data sheet application circuits for items such as RF switches, amplifiers, etc. (e.g., http://www.hittite.com/product_info/product_specs/switches/hmc349lp4c.pd f) use what I would call "microstrip traces surrounded by a ground pour 'guard' to reduce coupling to adjacent traces." Someone else, however, has suggested that the application circuits were really designed as co-planar waveguides (with grounds). Anyone else want to venture an opinion?

For a 62.5 mil board, a 50 ohm microstrip's width is around 115 mils using FR-4 (k=4.7). Using TxLine 2003, for a CPW w/ground I have to reduce the gap to ~50 mils before the signal trace width reduces ~10% to ~104 mils. I take this to imply that there's not a lot of coupling between the signal trace and the copper pours (instead of the ground plane) until the gap width is comparable to the board thickness.

In general, my impression has been that the use of copper flooding is more to provide isolation between adjacent traces than to change the form of the transmission line, and the use of the picket fenced vias was to insure that a large chunk of copper pour didn't suddently turn into a resonator. Does that sound correct?

For RF power over just a few watts, it is very hard to get good
bypassing...VERY difficult..actually impossible. You want to make a good,
low impedance (inductance) path in the emitter. Impedances in RF power
stages are in the sub ohm range and anything can cause trouble. The
divider/emitter resistor method is only good at lower levels.

The diode bias is set up to give the correct class AB bias, just like in a tube. The circuit is designed to give the correct bias. I believe the circuit also must provide a low DC impedance to the part, but I better ask some of the PA gurus around here to be sure.

The diode has to be in thermal contact with the part to get tracking over temp. Ideally it should be "on the die" because there is a thermal lag and differential between the die and anywhere outside.

It is possible to put a very small resistor in the collector supply and use an active feedback to control the bias, but that is complex.

My guess is that it will be very non-repeatable. Not being an RF designed
product, it isn't tracked in manufacture and can vary..lots.
Guess #1a It can vary depending how it is formed...do particles touch and
support eddy currents or not.
Guess #2. It is a poor material for any RF work.
Guess #3 It is messy to cast into a usable form.

$0.02

Maybe that's $0.08

Their Application Note 17 ("Design techniques enhance isolation in
switch assemblies") talks explicitly about grounded-coplanar-waveguide
techniques. The evaluation boards for the "349" switches certainly
appear to use the CPW techniques discussed in AppNote 17, including
closely-spaced plated thru-holes to tie top and bottom ground planes
together.

> For a 62.5 mil board, a 50 ohm microstrip's width is around 115 mils using

> sound correct?

If by "picket fenced vias" you mean the projections outward from the
signal vias on the evaluation boards, I take those to be the plated
thru-holesdiscussed in AppNote 17.

Are you seeing something I'm not?

Interesting gadgets. Awfully small, but interesting; may have to
ask for samples and eval boards.

Hi Mike,

Thanks for the response -- I'll go and read that app note.

> If by "picket fenced vias" you mean the projections outward from the
> signal vias on the evaluation boards

I mean all the vias going from the top side copper to the ground plane.
Viewed from the side -- and with a little imagination -- those vias kinda look
like a picket fense. OK, maybe not so much, but I *have* heard this term
before; I'm not making it up myself! :-)

I have a car at a second home that sits for months without use and a marine battery that sits in a small sailboat to power a bilge pump and lights. For the boat, I found a flexible, waterproof solar panel at West Marine that keeps the battery fully charged. In 4 years I've never had to charge it with anything else. For the car, I use a Battery Tender Jr. to keep the battery "ready-to-start" and it works well. Rather than monitoring the battery's condition remotely, in both cases I just use the chargers and never have to worry about it. If the car has a lighter socket, power outlet that's always on you can just plug it in that way. http://tinyurl.com/k9w56 shows the Battery Tender Jr. and you can buy it for under $30 at places like Pep Boys.

With the low current needed for a trickle charger, just wire it to a cigarette lighter plug and drape the wire across the steering wheel. It would be hard to drive off without noticing it.

Another solution would be to wire a 3 wire 1/4" phone plug to it and a jack to the car in an appropriate location where it will unplug if you drive away. Connect the 3rd terminal to get power from the car's jack and use it as a safety circuit to shut off the charger if it is not connected.

A lot easier, more reliable, and cheaper than monitoring the voltage and calling your cell phone.

> The NE602 was an old part.

Speaking of the NE602 - the old one - I have a question...

Is my chip dead, or is 40 meters dead?

I recently got re-interested in RF and pulled out some old parts to play with. I wired up an NE602 on a breadboard (yeah, I know), with a torroid, some padding caps, and a varactor for tuning, and got is oscillating on what my scope (yeah, I know) claimed was around 7 mhz.

Lots of domestic AM broadcast interference eventually tamed, but then only shortware broadcast received at these frequencies (ie, tunes like AM should with a direct conversion receiver) - no ham CW. I do remember from way back when that I found the novice 40m band useless in the evenings and would hang out on 15m then instead. Is that still true right now?

I know the receiver isn't totally dead as I increased the capacitance, tuned it down to what my scope claims is 80 meteres, and heard CW. Added an old op-amp audio filter circuit from the handbook and it's almost useable on 80m, but tuned back up to forty and nothing but broadcast...

What kind of ballpark magintude of oscillation should I measure if I probe the tank (well, actually pin 7) with a high impedance probe?

Can't say anything about the health of your chip.

There are times when 40 meters is dead, or pretty weak. There are
other days when it's fine. Sunspot numbers have been quite low
lately. The Western States Noontime Net on 40 meters was fairly weak
today and was weak yesterday... the net controls commented that
propagation was horrible. For a couple of days before that,
propagation was excellent and signals were just booming in.

>Lots of domestic AM broadcast interference eventually tamed, but then

>true right now?

I don't ever hear much in the old 40-Novice band segment. There's
enough foreign-broadcast interference after dark these days to drive
most ham activity out of the 7100-7300 frequencies. There's usually
some CW pipping away down at the very low end of 40 almost any time I
tune around to check.

The phone segment on 40 is usually quite active during the day, if the
band conditions aren't too horrible, since most of the foreign
broadcast interference is heavily attenuated.

My impression is that 15 is as dead as a doornail after sunset these
days.

the most important reason for the "pouring" is to reduce the inductance
of the upper side gorund plane.
most of the relevant field in the microstrip is confined in the volume
between the microstrip itself and the gorun plane beneath. there is a
phemomenon called fring effect, whereby fields generated on the upper
side of the microstrip come into play, but that occurs only at
frequencies of about 5GHZ and above, not at the usual frequencies we
talk about. it belong more to the microwaves' people realm.
leave it alone under 1GHz. you don't have to worry about that effect at
lower frequencies.

Hi Andy,

I don't know if you want to do any experimenting. If you do, one thing to consideris to not use a 602 as the product detector in that conversion. I have done it last month and it worked ok but I didn't really see any difference in the performance of the receiver.
the original product detector, being made from diodes, was a low impedance device. Consider replacing it with a DBM, since you already have a low impedance source of 50 KHz LO. If you make the conversion the authors did you end up moving the components to use the oscillator in the 602 and end up having to attenuate the IF signal coming into the 602 also. My only concern is the frequency response of the packaged DBMs - they are speced at 500 KHz as the lower frequency limit. Maybe using them at 50 KHz is pushing them too far.
I DID make the power supply and audio amp mods. The audio amp, especially, is extremely crude. I can't believe Drake actually built their audio amp that way (Class A with a transformer). I used a simple little 380 IC mounted right next to the volume control and it works fantastic.
I haven't done the earlier mixer mods yet, but so far the improvements in heat reduction and consequent VFO stability are worthwhile.

Thats a high price for a dual-gate MOSFET. You can buy more modern
devices for a much lower price. The BF981 and BF961 make excellent
RF and IF amplifiers. If you shop around, you can get them for
less than a dollar. Surface mount devices like the the BF996S are
well under a dollar, even from notoriously expensive suppliers
like Maplin. http://www.maplin.co.uk

Hi all,

I'm interested in finding out what the state of the art is in low distortion preamps for HF receiving systems. Anyone out there have pointers to reasonable designs for a preamp with input IP3 above, say, +55dBm, with amplifier power requirements limited to half a watt, and a noise figure better than 10dB? IP2 should also be high--greater than +100dBm--though it may be acceptable to have a lower IP2 as frequency increases. Gain around +10dB would be good.

Cheers,
Tom

I certainly hope you're going to be willing to accept an
estimated/extrapolated rating for that last figure, and don't require
an actual performance test!

:-)

:-) Yes, I would expect the IP3 and IP2 to be measured with signals in the -10dBm to 0dBm range. AFAIK, testing IP3 and IP2 is pretty much always done at levels way below the intercept points. It would be a pretty non-linear amplifier that had IP3 and IP2 below its maximum output before clipping. With the performance I'm looking for, it means detecting distortion products down more than 100dB from the inputs, but that's something I'm up for. I do need to work on a little better combiner for my sources, though, so they don't intermodulate before going into the D.U.T.. I can get fairly close to the sort of performance I asked about with some modern op amps, but not across the full HF band.

Cheers,
Tom

I built a linear using two 4-400's. I used the Johnson ceramic
sockets (square type) that did have some holes which lined up
with the ones in the bottom of the tubes. I mounted the sockets
under the chassis FLUSH with the bottom of the chassis. I pressurized
the chassis with a 4" boxer type fan mounted under the tube sockets.
This fan was one of the high speed types that could move lots of air.
I also mounted a pair of the same type of fans next to the
bottles on the top of the chassis, blowing air from outside
into the chassis past the tubes. The air flow went through the base holes
and around the glass bottle. This is similar to the way the
SB220 linear was build, as with many HB amps. The tubes did not
suffer any heat effects, while the pair ran near the legal limit.

BTW, 4-400's work ok in GG, but they like more HV than their triode
counterparts. While a pair of 3-500's work well with 2500v, the 4-400
likes more like 3300-3500v to get the same output and IM figures.
So your tank circuit will have more "L" and less "C".

Hi Tom. Look for Anzac combiners, we used them to measure +55 dBm Ip3 on the VMP-4 amplifiers and didn't get measureable IMD from them at +6 dBm in.

John Thorpe (AOR 7030 fame) assures us that the simple MCL PSC 2-1 is blameless to 0 dBm.

http://www.aoruk.com/comments.htm
>
I had been having what appeared to be hybrid IMD using some Merrimac combiners, which totally cleared up by using DDS sources instead of low noise HP 8640's modified to remove the levelling crosstalk. The DDS's do NOT talk to each other and less attenuation for isolation is required.

Gimmee a hint on your "modern" op-amps. Split PSU's I presume?

hello,

After completing my AF amp and BFO, I'm in the process of doing IF/BFO diode ring mixer.
I understood that it is a good idea (or even mandatory?) to follow DBM with a diplexer.

I found one from http://www.qrp.pops.net/dip2.htm

My question is: how on earth should I wind those 10mH inductors? My calculations show that I should wind 487 turns on FT37-43 (which is obviously impossible), or 437 turns on FT50-43 (which is hard..but should be possible).

Any other ideas how to make 10mH inductors for AF diplexer?

thanks!

The best solution is a pot core. A molded inductor is ok, too, but you might have trouble with hum pickup -- the voltage produced by any field coupled into the inductor will be amplified by the whole audio chain. A pot core is self-shielding like a toroid.

Doug, a suggestion about "Longevity" for 4-400's (Actually, any thoriated-tungsten filament power tubes):

These tubes are very sensitive to filament voltage. Make sure the tube pins and socket are nice and clean and shiny (don't use any abrasives!).. Measure filament voltage at the socket. This is all to make sure the tubes REALLY get the correct filament voltage to the filament... It's 28 Amps for two tubes!

Tubes that are new or in good condition do NOT need the full rated filament voltage for full output. But if you do not have good AC line regulation at your location, it's hard to get it exactly right.

In Broadcast use, I modified some RCA and Collins transmitters by adding a "Sola" type voltage regulator on the AC line, and an adjustable autotransformer ("Variac" or "Powerstat") to feed the filament transformer. With all new tubes, I could measure the distortion percentage on the transmitted audio, and lower the filament voltage until the distortion just started to creep up. And set a little margin. As I recall, a 5.0V tube would initially run fine at 4.6 to 4.7V. On one transmitter, the tube life went from 4000 hours to over 9000 hours (a year, 24-7). Of course, the filament voltage was slowly raised, and the tubes were 'retired' when the filament voltage for low distortion got up above 5.0 volts. In noncommercial service, you could get some retired 4-400a's to work for another 1000 hours or more by raising the voltage to 5.1 or 5.2

-- Plenty of air
-- Clean bright tube pins and sockets
-- Minimum required filament voltage

were the main considerations.

Have fun!

,,,,,,this is PRECISELY what a CPW is NOT!
A coplanar wave guide relies on the ground planes colocated on the same side of the board with the microstrip. there is no ground plane underneath. As such there is nothing to connect with through vias. This is a technique widely used in order to reduce crosstalk efects on PCB's when shielding and/or separation are not an option. The electrical field present upon the "fence" acts as sort of a shield and this help reduce coupling. Not much, but every single drop helps. It is quite similar with the DC guard ring used against lekage. The difference lies in the fact that at higher frequencies an elctromagnetic field rather than a purely electrostatic one is formed. You can see that it isn't a CPW when you reduce the separation. You have to go down to tenths of millimeters before you see the effect occuring.

Why go through all that bother? Look on ebay for a solar panel. There
are a ton on small units that VW uses to keep the batteries topped off
while the cars are in transit. They are small 5-10 Watt units. Usually
go for about $10. Lay one on the dash and park the vehicle so the
windshield is facing south. The unit has a cigarette lighter adapter
and you just plug it in.

aadu.adok@gmail.com wrote:
> My question is: how on earth should I wind those 10mH inductors?

In years past I would pick up 88mH/22mH and like "phone company"
toroids at hamfests etc.

My understanding is that these were used to compensate for line loading
in long phone wire runs.

Windings were either used as-is (if 88 mH or 22mH was appropriate) or
were removed and rewound.

Don't know what the actual core material was, I'm sure it was
completely inappropriate for RF but did fine at audio (I used them in
RTTY demodulators).

Haven't seen these on the surplus market in many years now. Too bad,
just about every 70's-era ARRL handbook had a half-dozen projects based
around them. A quick look at Digikey turns up some 2 through 16 mH
toroids intended for use in switching power supplies (page 1619).

==========

88 mH loading coils were used on 300-3,600 Hz phone circuits ever since around the years 1900 to 1910. Spaced every 2000 yards in 542-pair underground, long distance cables between phone exchanges and towns and cities, they were an international standard of loading. Countless millions were manufactured. 88 mH coils must have outnumbered all coils of all other values of inductance put together. Originally the core was a bundle of soft iron wires but in the 1950's after 50 years they changed to ferrites.

22 mH coils were another popular value. They were used on "music" circuits. Spaced every 500 yards the frequency range was 100-15,000 Hz. At one time used on a network between radio broadcast studios and transmitters.

Coils had to be removed to make cables suitable for carrier telephony and then digital transmission. But there must be millions still in use around the World.

Hi Saandy,

"+100dBm second order intercept" means that second order distortion products, following a simple small-signal second order model, would become equal to the input if extrapolated up to +100dBm. Second order products increase in dB amplitude exactly twice as fast as the fundamental, so that means that, say, a -10dBm input would produce an input-referred second harmonic of -120dBm, or -110dBc. If you decrease the input to -20dBm, the second harmonic drops to -140dBm, or -120dBc. If you increase the input to 0dBm, the second harmonic increases to -100dBm, which is also -100dBc. Extrapolating those numbers, you get a +100dBm second order intercept. In no way does it imply that the preamp (not all that low noise at a 10dB noise figure) can put out +100dBm, or can handle even +10dBm input without clipping or serious compression (though it would be nice in this case to get to close to that input level before clipping). Of course, distortion rises very quickly as you go into compression/clipping.

Similarly, a +55dBm third order intercept implies third harmonic at -110dBm for a 0dBm signal. In other words, I'm looking for an amplifier that has about equally good second and third order distortion products for inputs near full scale. I don't want super-good TOI without also having second order products low.

Cheers,
Tom

I would be looking for a core with bobbin to make winding a lot
easier. Something like this:
http://cgi.ebay.com/FERRITE-TRANSFORMER-CORE-ASSEMBLY-WITH-BOBBIN_W0QQitemZ7597936903QQ
Is an over sized core, but would work. One 1/4 this size would also
work. I would add a thin gap (sheet of paper) between the core
halves, to make the inductance stable. You can chuck the bobbin in a
variable speed drill, by passing a bolt through it, and wind hundreds
of turns in a couple minutes. You can adjust the inductance with the
core gap, if you have a way to measure the inductance.

Since I really need wider bandwidth than the super-low-distortion ones
will give me, I'm not remembering those off the top of my head.
Well-at AUDIO, you can get distortion down in the -140dBc range for
outputs at a couple volts RMS with either the OPA627/OPA637 or the
AD797 at low gains, and the '797 also has about a 4dB noise figure for
a 50 ohm source. But for wider-band RF stuff, the OPA847 is one
candidate, if used carefully. It's not quite as good as I'd like to
see, but close.

Cheers,
Tom

I'm curious, is the virtual ground at the input of a modern
high-bandwidth op-amp (set up with unity or only moderate gain) good
enough at frequencies of concern that terminating the mixer into this
with a resistive network would produced the needed lack of RF
reflection?

I know that in terms of the audio frequencies, op amps with R and C
passives have long been a viable option to big inductors - but can they
now satisfy the need to terminate the RF components?

1714. Re: Picket-fenced ground gias next to microstrip traces

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-09 22:51:27 UTC
From: Steve Nosko <suteuve.nosukowicuz@moutouroula.com>
Message-ID: <duqbhgdv2@engnntp2.cig.mot.com>
Source record: 13215

This appears to be a blend of co-planar and microstrip. Co-planar has no
ground plane, that is, everything is in one plane thus the name "co-planar".
A "microstrip-like" line is flanked by two ground surfaces and there is no
ground plane under it.
Like this
---- - ----

Microstrip is a flat line over a ground plane. Like this
-

The vias along both sides of this "CPW" T-line appear to be used to
constrain the fields and

The Vias most certainly must enter into the characteristic impedance
equation since the spacing to the line is so close. Therefore the line must
be narrower than pure coplanar.

I was part of a program to design a family of his same type of switch on
GaAs, back in the early 90's and the co-planar line was used.

news:duqbhgdv2@engnntp2.cig.mot.com...
> This appears to be a blend of co-planar and microstrip.

The freebie program TxLine 2003 "knows" about (can compute dimensions from impedances, etc.) CPWs, CPWs w/ground planes, microstrips, etc. and you can get some feel for how wide you can make a CPW w/GP gap before it's effectively a microstrip -- when the signal trace widths became nearly the same. I dug up some more Hittite app notes, and it does seem as though they're clearly playing in the CPW w/GP arena. They do point out that a major downside is that you eat up a fair number of routing channels with all those vias.

> I was part of a program to design a family of his same type of switch on
> GaAs, back in the early 90's and the co-planar line was used.

I'm surprised just how much "chaos" there seems to be in the RF IC (primarily MMIC) arena... there are plenty of old standbys like Hittite, MA/COM (now Tyco), and Watkins-Johnson, but they seem to have a pretty well stocked "stable" of components and only introduce a handful of new ones every year. On the other hand, the little guys and mergers like Freecell, California Eastern, and RF Micro Devices seems to have lots of good parts that suddenly get discontinued, product introductions that turn out to be vaporware (a friend claims that RFMD is great for this -- their data sheets are really part of their marketing department, with specs drawn strictly from simulation -- they initially quote everyone a lead time of, say, 3 months, and if they don't get orders for large quantities, they just never fab the chip in the first place), and otherwise seem a little difficult to rely on at times!

> now satisfy the need to terminate the RF components?

I've been playing with this a bit in simulation, and came up with
something seems to work. Most likely it is either common knowledge, or
fatally flawed - would be interested to hear which.

What I started with is an op amp with a grounded non-inverting input, a
50 ohm resistor from the mixer output to the inverting input, and a 50
ohm feedback resistor from the op amp output to the inverting input.
With an ideal op-amp, the inverting input would match the non-inverting
input's ground with a virtual ground, and the mixer would be
resistively terminted into this at 50 ohms for all frequencies.

Two obvious failure modes come to mind. First, at some frequency the
op-amp feedback will no longer be able to maintain a satisfactory
virtual ground. I tried to address this with a capacitor from the
inverting input to ground. 220 nF seems to clamp it there below the RF
frequencies where a 1 Mhz gain-bandwidth op amp fails, but not roll off
the audio response too badly.

Second, in the presence of a strong intefering signal on the order of
volts, the op-amp probably can't drive enough current through the 50
ohm feedback resistor to reproduce this, so non-linear effects (and
intermodulation) may set in. I attempt to address this by shunting the
feedback resistor with a 470nF capacitor, to make the gain roll off
towards zero above audio.

There is some slight reflection at the transition frequencies, but it
looks like it can be kept very low. One major weakness of this circuit
is that the rolloffs are largely first order and thus gradual. Given
that the goal of the exercise was to avoid the use of large inductors,
one improvement might be to precede the mixer with some higher order
selectivity at RF or IF, where inductors, or even ceramic resonators
are easy to come by. Another obvious improvement would be to pad the
output of the mixer down by quite a bit, though that probably means
picking up some broadband noise from the op-amp when it is reamplified?

So far I've only played with this in simulation. Trying to think how I would test it if I were to actually build it. I have some access to a network analyzer and would guess I could use that to measure the reflection from the input that the mixer would see over a wide frequency range. Measuring the ability to handle a weak signal in the presence of a strong interfering one might be harder.

I got something very much like it that clips to the sun visor and plugs into
the cigarette lighter. We'll see if it does the trick . . .

I just bought a solar panel that plugs into the dash. We'll see if it
works. The van doesn't get a lot of sun where it's parked and the rear
windows are all heavily tinted so mounting it back there won't help much. I
may still have to go with some sort of detachable umbilical because I need
to be able to charge his scooter while it's in the van, since he still walks
from the van into the house with his cane.

Thanks for the info. Hopefully the dash charger will do the trick.

I've thought about that as well as the solar panels but the car's parked in an area that gets very little sun. My damn toothbrush can recharge without any wires - why can't the car (aside from the massive size difference!)?

> Another solution would be to wire a 3 wire 1/4" phone plug to it and a
jack
> to the car in an appropriate location where it will unplug if you drive
> away. Connect the 3rd terminal to get power from the car's jack and use

This is probably the most appropriate solution. I especially like your idea of wiring it so that if it is accidentally disconnected via a "drive off" that there won't be a live 12VDC plug lying in the driveway. I was also thinking of affixing the charging cable to a spring-wound reel so that when disconnected, it would retract into the reel housing. Not sure where to find one for 12VDC charging wire, but can probably make one from a retractable clothesline pulley.

The one downside to this solution is that sometimes, depending on weather and other factors, the van is backed in, not nosed in. I suppose recharge connectors on both ends would solve the problem. I think I'll end up getting RV connectors because another issue cropped up yesterday - the need to recharge his 24VDC powerscooter while it's sitting in the van. That means at least 4 separate conductors going to the van in addition to any supervisory wiring that I might need. My concern for those would be to waterproof them and make sure they didn't get clotted with road slime and become useless.

> A lot easier, more reliable, and cheaper than monitoring the voltage and
> calling your cell phone.

I'm still not giving up on the cell phone notification. It will tell me if the car charger wasn't plugged in to begin with! Whatever I do, I think I will incorporate the ability to determine whether the car is plugged in and if, so, what the charge level is.

Thanks for the insights, Bill.

That's the plan for now. Hopefully it will end the problem of run-down
batteries. I may still need to go the "plug in" route because I want to
also be able to charge my Dad's 24VDC scooter while it's loaded in the van.

1723. What do you call these devices?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-10 09:55:19 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <1212j86qjoboec6@corp.supernews.com>
Source record: 13224

At work we have these "do-hickeys" that look like a regular "tee" connector. However, it's meant to be used such that a signal passes through the "top" of the tee while the "leg" of the tee "picks off" the signal some 10dB or so down from the input. (The insertion loss is some fraction of a dB.) The pick off seems to just be a wire tip coming out of the backside of the connector (just capacitively coupled?); there's an adjustable sleeve that lets you position this tip closer or further from the through line; moving it closer creates better coupling, but also tends to decrease frequency flatness. The cool thing is that all ports drive 50 ohms, and the pick-off's output is surprisingly flat over more than an octave.

Any ideas? It's definitely not constructed the way I'd build a directional coupler -- even though it performs a somewhat similar function --, nor a "magic tee" (although I've only seem magic tees in the form of waveguides and transformer-based affairs for HF).

Thanks,
---Joel Kolstad

1724. 7/8 wave antennas?

Newsgroup: rec.radio.amateur.homebrew

Do these things actually work?

I have a 2m 5/8 wave that I use mobile, and am told that a 7/8 wave will give more gain. Can anyone confirm?

I'm told also that I can just take the 5/8 wave out and stick the 7/8 wave in and it will load up. I doubt this personally - can anyone tell me if it needs more or less inductance?

Any ideas where to get loading coils from in the UK?

Thanks all!

Well, the 7/8 wave vertical has about 1-1/2 dB more gain than a 5/8 wave, if you measure that gain at the angle at which each antenna's radiation is greatest. The problem is that while the 5/8 wave antenna radiates most strongly toward the horizon (assuming a large ground plane), the 7/8 wave radiates almost nothing at the horizon. Its radiation is maximum at about 40 degrees above the horizon. Great for contacting aircraft at a particular distance, but very poor for general line-of-sight and repeater use. At the horizon, the gain of the 7/8 wave is about 20 dB less than that of the 5/8 wave. This assumes a large ground plane, and relative performance will vary depending on the frequency and installation. But you can count on the 5/8 being much better than the 7/8.

> I'm told also that I can just take the 5/8 wave out and stick the 7/8 wave

Considering the lousy radiation pattern, I can't see why anyone would want to use a 7/8 wave vertical.

This line of reasoning (a longer wavelength is better) harks back to the days of mobile CB antennas. Manufacturers would advertise their mobile whips as being 1/2 wave, 5/8, 3/4 even 1 wavelength. None were even close to being that long physically. The claim was that they had that much wire wound up in them. One manufacturer placed a layer of aluminum foil over a portion of the winding allowing them to claim 1/2 wavelength (of wire) and still be 1/4 wavel resonant. In addition, the I squared R of the shorted coil improved their BW.

> At work we have these "do-hickeys" that look like a regular "tee" connector. >

We called these an "isolated T" when I worked in 2 way radio and used them to check for receiver desense in a repeater. The through ports were placed in the line to the antenna, while the isolated port was connected to a signal generator on the receiver frequency. We would disable the repeat function, turn the generator amplitude up until we got some value of quieting in the receiver, and then re-enable the repeat function. If the duplexer was mistuned (or was a cheap notch only type), or you had a dirty transmitter, you would hear the noise level in the received signal rise. The isolated port was needed so you did not transmit into the generator and cause the magic smoke contained therein to issue forth. ;)

Some repeaters were very quiet (Motorola for one). Others (brands will not be mentioned but they had horns on them) often showed several dB of desense. I spent many an hour trying to finesse a sow's ear into a silk purse by tuning for minimum desense. Ahhhhhhhhh those were the days..... ;) :)

What is Ham Radio?

It is becoming increasingly difficult to fly the flag for
decency and for civilised behaviour in Radio Hammery. Even
the Usenet newsgroups dedicated to the cause have degenerated
into a hotbed of abusive onslaughts by those who ought to know better,
the Nugatory Numpties who boast of an interest exceeding 10,
20, 30, 40 or even 50 years and yet who have proved themselves
incapable of even meeting the trivial exam standards set for
6-year-olds.
However, there still exists the fundamental basis on which Ham
Radio is based, and that will never die. This FAQ ("What Is
Ham Radio?") will be regularly published and will not be
shouted or bullied down. It is important that those of a
technical bent, who are the natural seed-corn of Radio Hammery
and who gravitate towards us to be the real novitiate, can
still find us, (and know that we are still here), their fellows.

-----ooooo-----

Please remember that this FAQ is a _POSITIVE EXHORTATION_
to you to exert yourselves to join our fraternity! (If you find
otherwise, then perhaps you are already classing yourself in the
mediocre groups of those who are criticised in the FAQ and from
whom we _MUST_ dissociate? If so - it's never too late for
a re-taxonomisation on your part - there's nothing elitist about
us, and we welcome all those who are prepared to put themselves
out in order to join our ranks!)

-----ooooo-----
So,.....What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

A possibly easier alternative would be to use a different connector.
Like the Anderson Powerpoles. This too would disconnect via
"drive-off", but it wouldn't accidentially short the 12V charger if the
plug happened to land on a piece of metal. Yet you wouldn't have to
worry about the loose plug on the van end shorting the battery either.

Hi Bobby:

Make sure the dash charger is putting out more current than the "on
board electronics" require. If, for instance, your total current draw
is greater than the dash charger can supply, you're going to wind up in
the same situation (dead battery). Additionally, (and at night time)
the current draw on the battery is going to go back to "normal", and the
charger may not be powerful enough to "keep up".

I found this in a "Froogle" search:

http://froogle.google.com/froogle_cluster?q=mounted+battery+chargers&pid=4854524895284469150&oid=2589900813912983575&btnG=Search+Froogle&scoring=mrd&hl=en

Although well written Mr Plod and in some places downright excellent I think you are making assumptions about what AR "really is" and imprinting your own views as being the gospel. Mind you there is nothing wrong with that and invites positive discussion. Things could also be very different in G land but my experiences are different. Just be careful presenting this to outsiders as being something other than your personal view.

You seem to dwell on the "difference" or "better than" that AR has over other radio services. Since this and the associated CB bashing that pervades this NG on a regular basis I guess you are in good company. You could roughly divide radio use into "CB related" "Amateur related" and anything else like public services and commercial. You then concentrate yet again on the CB vs AR debate.

In my view there has always been a blurring about what use CB vs AR is about. It's a double set of bell shape curves that overlap in a lot of ways.

The first thing you have to do when judging behaviour and use is to throw away the ideal world of what the law that was passed on the topic actually menas or is interpreted to mean. Such arguments as "go get your license and we'll let you experiment" are irrelevent in the light of what ACTUALLY happens in the real world. The law is suppose to reflect the community attitude and beliefs rather than force its direction. There will never be enough resources to enforce a law if a large percentage of those that affect it, ignore it! Yes there are undesirable people on both CB and AR bands. This however is a subset of people generally. You can be obnoxious just as easily without a radio as having one. What grade of license you have is irrelevent and it continues to happen.

There is a lot of social conversion on AR, husbands and wives use it as a contact medium, people exchange weather reports and QSL cards. Those that go on desert treks use it as a backup emergency system. There is a lot on inane chatter about all types of things simply to hear one self speak! Are these within the technical pursuit of the hobby? CB'ers experiment with antenna systems and propagation, do technically illegal things to their radios in the PURSUIT of making them work better. In the process they learn and enjoy their hobby like an AR user does. Yes the technical standard isnt likely to be as high but it is there.

There is NO brick wall seperating the use of the respective services. It is very blurred and overlaps considerably. There is no black or white view amongst most of those that use it. There are of course exceptions

that dont look at the real world and try to force their own misguided views as correct. There is however a continual case of "I am better than you because I am licensed" not unlike the "keeping up with the Jones's" habit of preening in ones own nest.

Unhappily though "decency" or whatever you like to call it is not just a function of radio users. Its the result of the way the world is changing or if you like a sociological problem just waiting to explode. The place is a lot unhappier, people are more willing to return to their animal instincts and anything that makes it easy to tread in your neighbours is fair game. I mean just look at this newsgroup...

Apologies for this post being OT in the other groups posted

I think someone needs to tell that to the lawmakers in the UK regarding
the speed limits on the motorways and the positioning of some of the
fixed speed cameras which are in areas that are NOT dangerous.

RF sampler. RF pick-off. RF tap-off.

I don't know if there is an accepted "standard" name, but I have seen many types. They're used for just sampling RF where a wideband response isn't needed. You can inject RF also. Flat over an octave...that's interesting. The cap-tap usually will give a rising response. I forgot what a magic Tee is...

Then I regret that it is likely that you are a CBer, or
a CBer-Masquerading-As-A-Radio-Ham. I very
much regret that you may have been misled into
a false sense of belief.

There is _NO_ common ground between CB Radio
and Ham Radio.

Ham Radio is a technical pursuit for gentlemen.

CB Radio is an operating hobby for idiots. (Save
when used in its original mode as a social communications
facility when it is then indistinguishable from land-line
telephony or GSM mobiles)

> Thanks for the heads up.

You're welcome. I figured this solution would be the best for you because you could also install a jack to charge your dad's chair and the output is a "tad" higher than the solar charger option. You'll need an automatic isolator, but that's a snap to find and install as well. I know you're not in Canada, but a store by the name of Canadian Tire (http://www.canadiantire.ca) has one (search on "battery charger" in "automotive").

In my experience, the "clamp" style ammeters aren't all that accurate when it comes to reading small currents. I like my digital multimeter and doing things the "old fashioned" way. :-)

Mind you, it'll mean you'll have to reset your dash clock and reprogram the radio buttons, but I figure you're more than capable. ;-)

The cap was largely balancing out some really lossy cable, I think. :-) And
"flat" to me is about +/-2dB in this case, which is a pretty crude definition,
I expect.

http://www.bird-electronic.com/products/product.aspx?id=115 is one
example of what you're talking about, I think.

It's nondirectional. Quite handy for monitoring RF (one of these plus
a cheap used low-bandwidth Tek oscilloscope makes a decent HF station
monitor) and for signal injection (e.g. IMD, desense testing).

Surely if the argument for the cameras was a valid one i.e. safety then the
slow down lights that flash at you to reduce your speed would be 100% better
than cameras which you sometimes don't even notice they are there until a
week later when the intent to prosecute letter drops through your
door...where does safety come in to it?, nothing to do with safety at all...
just revenue makers... so I agree with you...

What does it mean to be a real radio ham?

It means you have a real ham license. Anything else, including the rest of your post, is just one person's opinion, period.

Bill, W6WRT

Ah, but define a 'real ham license'. A lot of people in the UK think
the M3/Foundation licence is NOT a real ham licence! Herein lies the
problem!

Quote

1 This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio. = MAN

2 Thus a Radio Ham could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line = MAN

3 Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then = MAN

Sir with respect to you
this is error

I myself have heard on quite few occasions
women with their own stations / license G3`s 4`s and 8
and have met a female Radio ham
at the Canvey Island public Amatuer Radio Rally Sale
who was also a stall - holder

another licensed Female operater was a sales lady in an
Essex amatuer radio Shop, she used to go to the same
social club as me.

Keith
G8IFW
after this, I think look how many mistakes I make, loads of them.
I think i had better write better messages myself

In this context, it doesn't matter what individuals think. What matters is what the gummint says. If they call it an "Amateur Radio License" or the equivalent, that's what it is. IF they call it a "Citizen's Band License" or the equivalent, that's also what it is.

What you or I make of those is important to us but irrelevant to the original question.

Bill T.

> with this?

My recollection from Eimac tube spec sheets is that there must be forced-air directed upwards from the non-tube side of the tube socket and there are specifications for flow rate and pressure. Both the 3-500 and 4-400 (100 watts less plate dissipation) call for 5 v at 15 amps (IIRC) on the filament and that is a lot of heat. I don't know if the 3-500 is pushed closer to the limits on this but Eimac made a special socket (and chimney) for the 4-400 but many ARRL handbook amplifiers went for a much simpler socket. And, the Johnson Thunderbolt (I had two of them at one time) used a simple ceramic socket plus an under-chassis phonograph motor type of fan to blow air up from the bottom as well as an above chassis fan motor to blow more air around the pair of 4-400s for a 1 KW DC plate input level (with dull red cherry glow on cw carrier and a little less glow on SSB voice).

Beyond that, if you are thinking of running 4-400s instead of the 3-500z, you also need to worry about bias voltage a little and you would have to resolder the socket pins because the 3-500 is a triode and the 4-400 is a tetrode (need to ground the screen, as well as control grid). But I have run 4-400s in GG in a homebrew amp in the past.

You are wrong Mr Plod.

Try to open your mind up just a little, learn some new things and consider that your views are based on prejudice and a very narrow view of what the world is and should be.

How you live your life and what beliefs you have are your right. Dont however use them as a base frame of reference.

At least you used the word "likely". That implies statistical possibility. Something that you havent applied to CB vs AR.

There are also a large number of female amateurs. How do they fit into the "gentlemen" designation?

Please back up your assertions with statistical analysis with a sound technical base. ie Dont use rhetoric & prove what you say is true with specific data.

I do however congratulate you for not appearing racists. (ie I shouldnt be using a UK newsgroup...)

~~~~~~
"Flow rate and pressure" are nice, but the *only* important thing is the temperature of the tube at various points as specified by the tube manufacturer. If you are serious about proper tube cooling, use either a non-contact thermometer of some kind or thermally-sensitive paint to ensure your tube is within temp specs. Flow rate and pressure are a means to an end, not an end in themselves.

I think it is you who is, perhaps, analysing this thread
with a limited purview, and who is in the wrong.

You will find that the FAQ is very much an encouragement
for all to learn new things and apply themselves to improve
their lot.

I cannot see how your remarks below can be squared with
the exhortations and encouragements that are in the FAQ.

Please read the FAQ, perhaps for the first time?

The Baird system has been superceded by more modern techniques. In fact,
unless you catch up quick, you may miss out a whole generation of technical
improvements that have occured since "Stookie"

No it won't

How will you bend the beam? Do you propose that people look straight at it?

You would need to get the beam just the right width.

Just face it beanie, you're an idiot, nobody likes you, you have no life and you'd do us all a favour if you took an overdose of something fatal.....

We'll um if that document (after "So What is Ham Radio") was the entire FAQ that you published you only dedicated the first few paragraphs to what AR is about. The rest seems to be more dedicated to what it isnt and what CB is/isnt. True, it contains some more positive references to AR but you keep needling at CB etc excessively. As far as I am concerned it would have been far more meaningful to omit any reference to CB whatsoever. I suggest you rewrite it like this, post it and see what we think.

I dont disagree with your first parts. It is well written even if it is what I deem a too narrow view as to what AR is about. The bit about being gentlemanly is irrelevent to me simply because I was never bought up or lived in a class atmosphere where that term had any importance. This however is probably a language difference as I might ascribe possibly similar qualities to AR people in general. (eg willing to help, never being violent etc) Of course these qualities are dissappearing in the world generally so I suggest AR is tending to go the same way. I also take your section on competition being something that spurs us all on to bigger and better things as being a load of tripe. It is true that competition occurs, but I and many others I have talked to never see it as important at all. It is in fact the "leisure and social" side showing through along the same lines as getting excited over a football match! I experiment becasue I am interested in it, not because I want to be better than everyone.

If I was a CB'er I'd take your FAQ as a slap in the face and it would drive me not to even think about taking up the AR hobby. Perhaps that is your agenda?

I'll admit I dont know Baird and the Televisor stuff. (Beyond the "father of TV "stuff) Lasers though are can be pulse width modulated (PWM) to pseudo change the spot intensity. In a air comms environment they are pulsed at some "carrier" frequency and data then sits on top of that. At the RX end they have a filter at the "carrier" frequency so you dont get noise etc from other light sources.

Making a picture? Had a brief think about bending light but that physics is kind of missing in my brain! I think if you used a rotating mirror array on two axis in front of the beam you might get something acceptable, be a real cow to manufacture though. Syncing would be reasonably easy (assuming a standard TV picture signal) but I think the spot would be a bit large unless you wall projected it.

Colour wouldnt work BTW as the (laser) spot will be one freq only. This means any filtering or coloured mirrors wont work.

Those laser pointers sound like a nice cheap way to experiment with some short haul data comms as well.

Actually in amateur service filament voltage is not that big a worry. I think the excessive worry comes as a carryover from BC service where tubes are operated far below ratings and can be operated for almost 9000 hours per year.

In BC service, excessive voltage shows up in a noticable period of time since the tubes are operated 24/7. The voltages and currents of other elements are a much lower percentage of maximum compared to amateur service, and filaments are not cycled. As such, emission failures are a common failure mechanism.

In amateur service, it takes many years and thousands of fialment cycles to accumalate the hours a BC tube sees in one year. Tubes in amateur service much more often fail from seal leakage, element structure defects, and occasional abuse.

Out of hundreds of tubes I've seen fail in amateur service over the past 30 years, I can count the number of emission failures on my two hands.

I'm not saying filaments should be run extra hot, but I am trying to point out what worries BC stations is often not a concern in amateur use.

By the way, two of the emission failures I saw were in 8877 tubes that were operated too cold. The owners had reduced filament voltage below 4.75 volts. NEVER run a MOX cathode tube at reduced voltage unless you also plan to limit peak emission current.

My advice is to run all tubes in amateur service at RATED filament voltage or in the allowable tolerance range for voltage.

As for cooling, seal cooling is critical in glass tubes. So is periodic operation to keep the tubes gettered.

Ok ta

I remember seeing a colour wheel project some years ago whereby a B&W TV set could be used to watch colour images. The idea was to alternate the displayed filds in sync with whatever colour filter was in front at the time.

I didnt make my original comment real clear either so perhaps it is worth fixing.

Laser light is coherent and of one frequency - ie monochromatic.

It was the name given to the receiver end of the Baird
mechanical TV system, used by the BBC before
Britland went out and started WWII.

30-line picture, transmitted in audio bandwidth.

A similar scanning system appears (from the nature
of the picture) to be used in some of the security
cameras that rely on detecting bodily emissions.
(Difficulty of getting a sensor that can work over the
area of a pictur)

Played with it last night.

Powered as it is by AAA cells, it seems to have
a greater power, and a greater reserve of power, than
those laserpointers powered by watch batteries.

Allowing for the lens that is used to produce the
straight line beam, the spot from the end was
easily picked out on a gravestone 1/4 mile away,
thus suggesting that a tight beam is being produced.

As these beasties come in a mounting that already
has facilities for screw fixing, perhaps there is
potential capability for optical communications?

(Brian - in your experiments with the Fullerphone, you
ran away from the question as to whether you crossed
a property boundary, so....

1. Did you cross a property boundary?
2. Why do you run away from this and so many other questions?
3. Is your attitude what we must all now expect from the RSCB?)

Given the relative size of AAA and "watch batteries", this is hardly
surprising.

Laser's are coherent sources, the "ASER" stands for Amplification by
Stimulated Emission of Radiation- the crucial phenomena in the operation of
lasers and masers. The emitted photon is in phase with the stimulating
photon.

> As these beasties come in a mounting that already

Been done. UK record, as of a couple of years back at least, was something
like 75km. There is project in the latest RSGB handbook (if you are
interesed I'll look up the page, I noticed the article but haven't read the
detail).

Invasion of Poland (Fall Weiss)

On August 31st, Hitler signed Directive No.1 for the Conduct of the War and the order went out at 4:00pm to invade Poland at 4:45am on September 1st of 1939. That night SS units staged incidents along the border including a phony Polish raid on a German radio station at Gleiwitz (Gliwice). Before sunrise the next morning, Friday, September 1st of 1939, World War Two began. Germany invaded Poland, the German attack beginning at 4:45am, when the Battleship (training ship) "Schleswig-Holstein" (on a so-called "goodwill visit") opened fire on a Polish naval depot and garrison at Westeplatte. An hour later, first German units crossed the border. On September 3rd, 1939, Great Britain and France declared war on Germany.

Many years ago Practical Wireless had adesign for turning every ready
torches (the ones with the big 9v batteries) into a transmitter and receiver
by amplitude modulating the bulb.
It actually worked (over about 20 feet).

Remember it (or one like it) well- it was one of the many projects I tried
as a youngster. (Same sort of time I played with the Fuller Phone).

With a laser pointer but I'm not sure how linear the transfer function is-
ie is it linear enough to make AM viable. I've not looked into this but
maybe someone will know.

Well, quite.

The shortest Google search would have turned up the information needed
to avoid him making such an obvious statement. A CR2032 battery has a
capacity of 220 mAh at a current drain of 0.2 m/A.A modern AAA battery
far exceeds that - I've left it as an exercise for the OP to search
for that info..

>> Allowing for the lens that is used to produce the
>> straight line beam, the spot from the end was

A 'tight beam' would indicate a spot not much larger than the laser
source. Unfortunately, the lack of *any* objective statement in the
above gives no indication that the beam was 'tight', merely that it
reached it's target.

Does anyone know of a UK source for "Wainwright Mini-mounts"? These are small PCBs made in Germany by WMM GmbH (no web-site or email!), laid out to take an IC, with tracks from each IC pad taken out to the edge of the PCB - very useful for prototyping with TSSOP devices it seems.

If they sound interesting, see:

http://www.rdi-wainwright.com/

which is the site of the US agent - $100 min order!

Your underlying motivatiopn to pooh-pooh makes you
seem like a fool.

It is the optical path that determines the divergence, or otherwise
of the beam, by dispersion, diffraction, refraction mechanisms,
and not the coherence of the radiation.

(Cue rejoinder by Mrs.Nugatory, given 5 minutes or so, to look
things up on google, to say that monochomatic radiation is
unaffected by a dispersive medium.)

Your deep-seated motivation to pooh-pooh just serves to
make you look a fool.

If you, as a director of the RSCB unfailingly try to put down
discussion, then perhaps it is a sign that any self-respecting
REAL Radio Ham should resign from the RSCB?

There are many things which have "been done" and yet which
you do. (Apart from a Morse Code test that had "been done"
by otherwise-unqualified self-taught 14-year-olds).

HF Communication had "been done" by thousands, long before
you purchased all the Cheque-Book (CB) rigs that you boast about.

I don't think that I have ever been "interesed", whatever that may
mean.

Eh, no.

A laser will diverge in the absence of a medium.

Degree of collimation and coherence both are factors in divergence and you are jumbling together a raft of factors that I supect you don't understand and I know you don't want to learn about.

Source record: 13107

Hi all.

I'm trying to find a good circuit for a Class C 4CX250B linear.

I've found a few for multiple valves in Class A, but I'm after just a simple circuit that shows a 4CX250B linear for 2m with Class C biasing.

Idea is to use it for a little project where I want to run about 100W, but run it cleanly without all the RF hash that transistor amps give.

Can anyone point me in the right direction?

Also, how would you go about varying the RF power output on a 4CX250B linear in class C? Is it by varying the 1.2kV supply voltage, which would make sense, or is there some other recommended way?

Sam

1807. Re: 7/8 wave antennas?

Well, you're the expert in behaving like that, and as you
practised it for over 20 years, it probably accounts for
it being uppermost in your mind.

How come you never managed to pass a 12 WPM Morse
Test targetted at 14-year-olds in all that time?

Are you, perhaps, too lazy or too stupid, or both?

How come your objection to a Morse Code exam
being used as a filter to control access to HF suddenly
disappeared when a test down at your level, ie, targetted
at 6-year-olds, came along?

Hypocrisy, perhaps?

"Do as I say and not as I do", perhaps?

Bullshitting and downright lying, perhaps?

Is such two-faced behaviour that to be expected from
all directors of the RSCB?

Brian Reay wrote:

Mrs Nugatory appeared for a short time in uk.rec.models.engineering
masquerading as, "Novae Artless", but her modus operandi gave her away;
in particular her plagiarising of google articles and attempting to
pass them
off as a facet of the skill which she doesn't have, her obsessive
sneering
at me, and the completely vacuous and nugatory irrelevance of her
contributions.

Will she ever be able to pass even an exam targetted at 6-year-olds
in her desperation to be accepted amongst the fraternity of
REAL Radio Hams?

Seemingly not - Mrs Nugatory and The Numpties are well named!

There is not really any difference in a class A and Class C circuit. Just
adjust the screen and control grid voltage to the class of operation you
want. Should be in any of the tube manuals.

Hi everyone,

I am in need of a complete multi wafer bandswitch 5/6 lugs for a set of 3-500Z.

Currently, the one installed is a single wafer, trying to hookup

a tuned input board. The amp i am working on is Hunter Bandit 2000C

which is 10-80 meters. Any suggestions, or have one laying around in your parts bin you can let go?

Thanks for looking.

So basically take off the bias?

I assume then that I can just use the tank circuit to tune it nicely?

And I might have to increase the drive by 4 times in order to get the
potential 4 times increase in output?

Sounds simple enough to me!

Sam

There are a few designs in the old RSGB VHF/UHF Manual. If you
are searching the web for info, leave out the word 'linear'.
A class C amp is usually not linear.

I use a single 4CX250B on 2M. The G1 bias control is on
the front panel so that I can adjust it to class AB for
SSB and class B or C for CW,JT65 or FM.

What is the efficiency of a laser device like nowadays?

I went to a 3D TV IEEE demo back in the 1970's where the device looked like a TV but had "depth". Kind of like those kids puppet theatres! The big thing I remember at the time was the huge power consumption (1000-2000W?) needed to produce even a moderately lit picture. It was said at the time that the appliance would probably never be marketed as a 3DTV in every house would flatten the electricity supply system every time a football/crickrt match was on!

I cant quite remember the physics or name behind the 3D technique. Some kind of inteference pattern generation maybe. The name escapes me...

Cheers Bob VK2YQA

Then you want to run it class AB1, which is much easier on the fragile
grids, BTW.
>
>

>sense, or is there some other recommended way?

If you would just forget the Class C part, you would simply vary the
input (drive) power and get a linear change in output power. Varying
the drive power to a Class C amplifier will change the output power
too, but in a "non-linear" way. Changing the anode voltage on a
tetrode to vary (DC) input power is fraught with trouble and doesn't
make sense.

If you insist on Class C bias, (grid cut off with no drive) and you
can't vary the rf drive level for some reason, with excess drive
power, you can bias the grid further into cutoff. This will increase
the harmonic content, but the plate capacitance of these tubes
(valves) is high enough that the Q of the plate tank will be
necessarily high so this may not be an issue.

You might consider changing the screen voltage. Be advised, however,
the screen grids in the tubes are very delicate and you will have to
insure that dissipation limits are not exceeded.

The current UK laser record is around 73km I believe... held by G0MFR
and G8LSD. They used standard low power red laser diodes of the kind
found in the pointers. Barry,G8AGN, Gordon G0EWN and myself (all in
Sheffield) are also experimenting on these lines have done a 45km path
so far... using cw. We have some LOS paths up here in the North up to
136km so we're hoping to better the record one day soon :-)

You don't take it off like you would a transistor. Tubes work sort of backwards from transistors. YOu increase the voltage to the recommended value of plate current. Somewhere around -50 volts for AB and -100 volts for C. That would give around 60 ma of plate current for AB and very low current for C with no input signal.
You will need the tube spec sheet for closer values. Also the screen voltage should be changed for the mode if operation is for CW only. Think it is about 250 Volts for CW and 350 for AB but may have it backwards.

Oxymoron. Class C is NOT linear!
Now if you want to amplify CW or FM signals, class
C is fine. For AM or SSB signals you want class A, AB or B.
For this tube the grid #1 bias, grid #2 voltage and grid #1
drive (signal input) are different as you change class of
operation. (Mostly the screen and plate voltages can remain
the same and just change the resting plate current with the
bias and don't apply more than a specific signal level so
your max plate current isn't exceeded.)

If oversize filament transformers are used (never know what kind of
surplus junk hams use!) there is a danger of filament failure
due to starting in-rush current. My home brew linear started these
tubes up with a power resistor in series with the primary of the
filament transformer for a few seconds, which was then shorted out
by a relay. A transistor r/c delay circuit did the dirty work.
This lets the tube filaments preheat a bit before applying full
voltage.

You can try to home brew your own by attaching a shaft to the
back of the main band switch to gang to a second one.
If in your case, you want to add a tuned input switch this
is the best bet as the two switches should be of different
sizes (one high power one low). You might need to use
flexible shafting for the coupling, and gearing if the
two switches have different switching angles.

Unfortunately, you are making no progress whatsoever.

I merely mentioned some characteristics of a typical watch cell, suggesting that if the OP looked on Google he could have found it out for himself, thus avoiding posting what he did and looking like a fool. Is that simple enough for you?

>If we could now get you to understand what ' I can't think of anything
>else' means, then that would be real progress.

I know you like things kept simple, so I strongly suggest you never attempt to repair anything at all - you just don't have the brains for it.

No throwing away of a fine receiver here due to 'nerves', fettling, or missing pages from the manual. ROFLMAO. In fact, it directly follows the Gospel According to Gareth, in his (still unqualified and therefore dangerous) 'repair with gusto' creed; something he has admitted failing in the past. ROFLMAO.

Is that simple enough for you?

Sam:

If you want to run an RF amp in a linear manner then one cannot bias the amp in class C. Class C is not a linear mode of operation and will give all kinds of trash if running in SSB. Now if you are running either CW or FM, then you can run a class C amplifier.

The Most linear class of amplifier operation in the classic modes is class A mode. This mode means the active device is always conducting even when the input is not being fed any signal. In an ideal world efficiency of class A is only going to be 25 percent.

Most amateur class amplifiers run in a mode that is either ABone or ABtwo. I can't recall the differences between the two at the moment but they are clean under normal operation and don't put out a lot of noise.

Hello to everybody.

I would want to use a pair or quad tetrode (4-400a or 4cx250/350) as GG
triode for AB/C class operations.

I don't remember where I have read that only the control grid had
physically push to ground, while the others grid(s) was electrically
floating and connected to ground through of the capacitors....

Can you help me with schemas, links and suggestions?

Many thanks in advance..and sorry for bandwidht...

AFAIK a tetrode in grounded grid doesn't give you much more (if any)
gain than a triode in grounded grid, but you still need all the special
care and feeding of the screen.

So why not just use triodes?

Better yet, why not use the tetrodes in common-cathode service, and get
1000 watts out for 1-10 watts in?

~~~~~~
The control grid should be connected directly to ground but never allow the other grids to float. They must either be connected to a standard bias supply or grounded themselves. If they are floating, they will pick up a charge and do things you don't want them to do. :-)

Connecting all grids to ground was a common practice in the old days but is rarely done anymore, due I believe to bad linearity. If you're only doing CW, FM or RTTY, linearity is not an issue and it should work fine that way.

I agree with you opinion.

> So why not just use triodes?

My experiences are only in triode PA and I have a lot of tetrodes and
pentodes "unemployed" :-)))

> Better yet, why not use the tetrodes in common-cathode service, and get

Sure, but I don't have experience in tetrode or pentode PA and the screen
grid managenement, isn't a walking...
In all know books and websites I don't find a valid explaination of this
matter....

Thanks!!

Hi

Class C isn't fine.
Class C is producing a lot of harmonics
Specially odd ones are bad.
I don't recomment class C elsewhere but for transistor FM use in VHF and
UHF
Maybe also for KISS QRP in HF CW

How to adjust DC grid bias, screen and plate voltages, RF grid-drive
volts, to provide a given plate-current operating angle, is shown in
program OPANGLE3.

It is the plate current operating angle which decides which condition
the amplifier is operated under. Program OPANGLE3 covers covers
class-AB, B and C conditions.

By connecting BOTH grids of a 4-400A or similar tube to ground you are creating a high mu triode out of a tetrode/pentode/beampower tube. Nothing wrong with that, but triodes made specificly for the purpose do work better. Now if you happen to have gotten the tetrodes surplus, or they are already in the junk box, use them, they make good grounded grid amplifiers.

The "triode" grounded grid connection does not require neutralization, bias, or screen power. It DOES require more driving power. You can also apply normal grid and screen voltages but ground the grids (for RF) with capacitors and apply drive to the cathode as in grounded grid. This is called "cathode driven". A cathode driven tetrode requires no neutralization and needs less drive than a true grounded grid amp, but more drive than grounded cathode (grid driven).

BTW not all tetrodes can be driven in true grounded grid. The 4cx250 for example, can ONLY be used in cathode driven or grid driven service. If you try to run it as true grounded grid you will MELT the grids!

1845. RF power transistor - CM10-12A datasheet, and stock

datasheetarchive.com list the MRF641 as a possible substitute.
The MRF641 datasheet is readily available. A comparison with
the specs below shows that they are quite similar but not
identical.

The following specs are also from datasheetarchive.com
Part Number = CM10-12A
Description = Bipolar NPN UHF-Microwave Transisitor
Manufacturer = Various
V(BR)CBO (V) = 36
I(C) Abs.(A) Collector Current = 2.5
Absolute Max. Power Diss. (W) = 35
Power Gain Min. (dB) = 7
@V(CE) (V) (Test Condition) = 12
@Freq. (Hz) (Test Condition) = 470M
@I(C) (A) (Test Condition) = 10
@V(CE) (V) (Test Condition) = 12
@Freq. (Hz) (Test Condition) = 470M
Semiconductor Material = Silicon
Package = SOT-119var

Hi Ed,

Yup, I found the 641 also, the thing which is odd is that the CM10-12A is designed for linear while the 641 is FM class, I am surprised that they were crossed. The CM10 is supplied with a matched thermistor, and I doubt that it will track the 641 correctly.

I have a low gain CM10 and I think that direct replacement is the only way to go.

Thanks for looking

Hi,

I had exactly the same issue a few months back. Winding so many turns on a FT50-43 is not realistic. Actually, winding the same number of turns on any core, even the pot cores recommended by other people are not so good for this application. The issue is the parasitic capacitance. In my case, I needed ~2mH inductors. After I wound the required number of turns on FT50-43, which was about 60 (IIRC), then measured the parasitic capacitance, it was too much. The self resonance was somewehere in the below 1 MHz. The 60 turns just about fits onto the core. If you go for second layer (and beyond), the capacitance will skyrocket.

A diplexer is supposed to provide close to real, near 50 Ohm impedance to the mixer. At the same time, it needs to work as a low pass filter, to keep the RF out of teh audio stages. If you do some simulations of the common audio diplexer topologies and take into account the parasitic capacitance of the inductors, you'll find out that the match is close to 50-Ohms real only at audio, maybe up to LF. Completely useless at HF and above.

So what's the solution? A few options:
1/ Try a material with higher permeability. Toroids are best, because they don't need shielding and they don't break as easily as pot cores. I'd recommend FT50-J. This is I think the highest permeability that Amidon sells. You should end up with much smaller number of turns. It may improve things in your case.
2/ Forget diplexer. Use an attenuator, followed with a low pass filter. This will increase the noise figure & gain of the mixer-post-amp combo, so you'll have to make it up with more gain ahead of the mixer. But you'l have higher IP3. You could set the amount of attenuation to balance the noise figure against IP3. Where the optimum is, I have no idea.
3/ Since you are mentioning BFO & IF, I assume that you have a superhet. The mixer at the end of the IF strip does not have such hard requirements, since you've already filtered the 'bad guys' out. For SSB, you would not care about intermod performance after IF filter too much; well maybe except for audio distortion. Actually, for a product detector in a superhet for something like SSB, don't even use a diode mixer. Too much power and not necessary. Switch over to an active mixer, like the NE602.

Anyway, your mileage may vary. The above should work for common cases. If you really need a proper broad-band RF diplexer which also works as an audio low pass filter, then you're in for an interesting journey...

Hope this helps,
Fil

Hi Mike,

One option is to try the hybrid power modules. A lot of these are listed at http://www.rfparts.com/module.html. For 432, I'd try http://www.rfparts.com/pdf_docs/RA/ra45h4047m.pdf. Low drive though - so maybe not exactly what you're after. But you get 50in-50 out, no hassle. Combine a number of these to get desired power.

73,

Yep, that's them alright. The one we have is the electrostatic version.

I took a closer look over a wider frequency range at its response and -- not too surprisingly -- it's a straight line on a log-log plot (i.e., the coupling is almost purely capacitive).

Thanks for everyone's help,
---Joel

Yeah. for 50-12000 MHz. 6m and above and not much use for HF, then.
Good thing they've got a feedback E-mail address, but I suspect that
they'd want lots'o'$ for a one-off modification.

I suspect you could make your own for HF without too much difficulty by
modifying something like a SO259 tee along with a standard PL259 connector.

On the other hand, for HF you can make pretty decent directional couplers
using transformers and get a significantly flatter response if you're looking
to accurately measure signal levels.

I can't find the answers to these in the books and I've wondered about them for years.
When winding a coil on a standard (say 1/4") former with ferrite or iron dust core, should the secondary be wound adjacent to the "hot" end of the primary or the earthy end? Also, should the earthy end of the secondary be adjacent to the primary hot end or earthy end?
What's the difference between dust iron and ferrite cores and can you tell the difference by just looking at them?
Thanks. Howard.

Usually you would wind the secondary on the ground end of the primary, because you'll get less capacitive coupling from the primary to the secondary. The direction of the secondary probably matters much less.

Iron dust cores are made with various different iron compounds ground to dust and bound in a matrix of some sort of plastic (they probably use epoxy or phenol, but I don't really know). Ferrite cores are made with various different ceramics that include iron. The surface of ferrite cores usually look more solid, less porous. Iron cores can be scratched or cut with steel tools. The ferrite cores I've used are quite hard.

Just knowing that a core is iron or ferrite won't help you much, because there's a whole bunch of different mixes of each.

Ferrite cores usually have higher permitivity, which means more inductance for the same number of winds. They also usually saturate quicker, which means that they aren't as good for resonant circuits or for filters.

Tim W. wrote, "Ferrite cores usually have higher permitivity, which means more
inductance for the same number of winds."

Presumably he means permeability.

You should be able to find both downloadable programs and web applets which let you find the inductance for a given number of turns, for a core of particular dimensions and permeability. Using that info, you can go back to permeability if you measure the dimensions and an inductance with a known number of turns.

There are also fairly standard color codes for powdered iron toroids, though, as they say, your mileage may vary. But in general if you find a permeability below about 50, it's very likely a powdered iron core, and above that it's much more likely to be ferrite.

You can find some good core info at the Amidon Associates web site, or at least could the last time I looked. A Google search should turn up lots of other references.

Cheers,
Tom

Yes, he did. They may have more permitivity, as well, but since they're
rarely touted as a dielectric it doesn't make much difference.

AFAIK the color codes vary by company. There is probably overlap, but I
don't think it's "standard".

********** REPLY SEPARATOR **********

The earthy end. (Love that term!).

Winding over the hot end will cause capacitive coupling in addition to
the magnetic, something generally not desired.

Hi Samuel and all
>
> I'm trying to find a good circuit for a Class C 4CX250B linear.

cough *cough* *choke*

A Class C is *not* linear.

I think the usage of "linear" for "an external amplifier to boost
the power going to the antenna" comes from the CB crowd, who *do*
need a linear amplifier (for SSB).

OK, you want to boost FM, and for that you can use Class C. The
only ARRL Handbook I have here (1992, I'm not counting the '48 :-)
has two very similar schematics, one for a 3CX800 and the other
for a 3CX1500, but I do seem to recall that a different edition had
a 4CX250 schematic. Or maybe it's the RSGB handbook.

> I've found a few for multiple valves in Class A, but I'm after just a
> simple circuit that shows a 4CX250B linear for 2m with Class C

The Pomona die-cast boxes with card mounting slots and prefabbed for BNC's are the glitz, man. (And it's not easy to die-cast all that stuff on, probably explains why even the little boxes can cost $70.)

Bud/Hammond/etc. make much less glitzy die-cast boxes for a lot less $.

Maybe our eternal squire wants to use CNC machines to make boxes out of aluminum ingot? :-). Take the scraps, melt them down, repeat!

Tim.

1876. Re: focus group question for new products

Newsgroup: rec.radio.amateur.homebrew

I find that boxes are generally too expensive, and rarely the right size.

Generally, I want a box for the desk, so it typically could stand to be fairly deep -- say 7-10 inches. I also want it wide enough for a few controls and an LCD, so maybe again, 7-10 inches. The height generally seems to be the problem. It seems like boxes are either an inch and a half high, so you can't get a display in there, or 5 inches, way taller than necessary. I would think that 2.5-3" high boxes would be awfully handy, but they seem rare.

And of course, they tend to be horribly expensive.

Card guides inside would be nice.

Aluminum would be nice so that it is easy to machine. Although in reality, some sort of lined plastic might be better.

Thick enough to be strong, but thin enough that it doesn't weigh a ton -- plus, a thick panel looks junky in front of a display.

Powder coated would be nice, but at least some reasonably clean finish so I don't have a ton of work to do before painting.

I often use plastic boxes with a removeable, flat panel. I can replace the panel with plexiglas, so that instead of trying to make a square hole for the display, I can simply mask off a square hole. As an added bonus, my labels are protected by the plexi. Unfortunately, these kinds of boxes aren't RF tight. In an ideal world, I would have that sort of box, sprayed on the inside with RF proof paint, and with an insert I could place behind the display to make the front RF tight too, while still allowing for the display. Pipe dreams I guess.

1880. Crystal replacement

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-16 05:31:20 UTC
From: Joel <Joel@cyberbest.com>
Message-ID: <1142486941_139@sp6iad.superfeed.net>
Source record: 13081

I have a couple 6 channel public service radios that are in the 155Mhz range. Some are synthesized and require cutting diodes to change the frequency and that works out well.
But some are crystal controlled and with the cost and availability of crystals it's cost prohibitive to re-crystal these radios. It looks like these crystals are in the X9 mode so that puts them in the 16-16.5 MHz range. I am considering building a VCO to inject a signal into the old crystal socket to get around the crystal issue. Actually I figure a PIC to program the PLL would be great. I'm just not sure what frequency to inject into the old crystal socket. Should I build a 16mhz VCO or some harmonic? Will injecting a signal into a crystal-less oscillator even work? I'm going to use a ADF4110 PLL and a 16F89 PIC. Any suggestions for the VCO? Schematic for a 16 MHz VCO?

It depends on mode, reference frequency, et al. VHF-FM and VHF-AM are remarkably less sensitive to crap coming out of the synthesizer than say HF SSB operation. I shiver when I look at the 50's and 60's ARRL handbooks and see construction articles for 2M and 70cm transmitters using a tube VFO at 8MHz multiplied all the way up!

All that said, chips made specifically for VHF synth operation (MC145170) are available as are kits using these marketed towards hams (e.g. http://www.dckits.com/) who want to play around and learn. It's not a guarantee that you won't be radiating crap all over the public service frequencies of course (that is the biggest risk here, isn't it?)

Tim.

1886. FM S:N and C:N relationship?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-16 18:09:24 UTC
From: Samuel Hunt <shunt010@hotmail.com>
Message-ID: <dvc9kk$8ho$1@nwrdmz02.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 13087

Does anyone know any sort of a formulas that might give me a clue as to the relationship between S:N and C:N for an FM system?

I'm playing with narrow FM (500hz deviation kind of stuff), and want to try to work out the expected S:N for various different deviations with different C:N radios. Obviously the C:N improves with lower deviation because of the tighter IF filter, but the S:N will worsen because of the lower deviation, but I would appreciate some sort of help in the right direction for the formulas.

Thanks all,

Sam

Look at how, for example http://www.pcbexpress.com/ and
http://www.frontpanelexpress.com/ do business. I could imagine a
business model not too different working for custom-machined enclosures
(and CNC'ed metal widgets in general.) Target audience would be
engineering firms that don't do this in-house and aren't set up with a
local vendor, hobbyists, etc. Maybe some customers that don't do this
at all yet (amateur jewelers? who knows!!!!?!!!)

One thing that those outfits have is free CAD software for
design/specifying. If you kept your options really straightforward
(e.g. boxes with round holes and square holes for example) maybe design
could be done over the web. (Dynamic graphic generation, or maybe SVG
with user interface.)

Tim.

Hi

The great advantage of ferrite materials is just what you said - more
inductance for the same number of winds.
In this way high Q coils can be done. A good example is direction
finding receiver with ferrite rod antenna for magnetical field component
of fox transmitter.

I agree that saturation can be a problem in higher power levells
Anyhow good high power baluns are made with toroids and filament chokes
with ferrite rods for grounded grid linears (Yes- they are not tuned
resonant circuits)

Tim,

After studying this, I have a question:

It seems to me that I should basically have a standard design with
options. I could then post the drawings as a webpage for people to
look at and specify those options. It will be a while before I can
consider making one-of-a-kinds for people, but standard specs and
stackable configurations I could do on a JIT basis.

Would that be acceptable for now until I could afford greater
sophistication?

Thanks,

The Eternal Squire

If its for commercial use it would probably be easiest just to get the crystals.
Otherwise designing a PLL system is possible - particularly if you want to learn about them for your own education. But the work involved is not trivial - probably not worth it for a few old radios. The other issue will be how the radio achieves FM - if it does it swinging the crystal, then this will impose another restriction on the PLL. While it is possible to do (keep loop filter BW below min audio freq) I tried doing this on a 2M design once - couldnt get it stable. Some radios phase modulate one of the multipliers, which would avoid this issue.

The idea is we have a few dozen crystallized Maxon 4010's here and figured
we could get them converted to 2 meters to give to the new ham's in the
area. We would do the crystal route, but crystals seem to be in the $12.50
or more range (If you can even find them) That means it would be about 25
buck/channel. The price quickly makes conversion cost prohibitive compared
to a new 2 meter radio.

I reversed engineered the Maxon 3010 as they are synthesized and by cutting
diodes we have them working on 2 meters. Of course, having a schematic for
either radio would make things a lot easer.. (hint)..

Here's another idea...instead of making these radios to hand out to new hams, maybe you could remove the transmit crystal and just replace the receive crystal, lowering the conversion cost. You could hand these out to NON-HAMS so they could listen in on the local repeater or simplex channel. Maybe they would be interested in becoming hams. 2M HTs are so cheap these days, just about any new ham can afford one with a lot of bells and whistles built in.

Scott,
I hear your point.. These are not HT's but 40 watt mobiles. I understand how cheap HT's are and that's why I can't see spending much resources on the conversion. But I'm always looking for new uses to implement PIC chips and interfacing one to a synthesizer seemed like an inexpensive idea. PIC and synthesizer cost together is barely 12 bucks.

I actually found your aluminum scrap thread on rec.crafts.metalworking, and I think it's pretty much hopeless to mill "standard" boxes out of aluminum ingots and make money.

I mean, frontpanelexpress has the advantage that they start with a sheet of the final thickness. Even a front panel with a lot of holes is still 50% of the original material - enough of a difference to matter for large scale production but truly negligible for small-volume stuff. OTOH you will be milling away 99% of the original block and you truly have to be creating unique value to make this worthwhile. At that point the energy cost of melting down all the scraps to start over again are probably more than the inflated retail cost of a die-cast or extruded box.

I think you've got to concentrate on quick-turnaround custom stuff. Just my opinion. And think about doing more than just boxes (although boxes with holes is probably a not-too-hard-place to start from.)

Or think about a way to do custom sheet-metal operations (shearing, bending, curving, punching, etc.) in a semi-custom way, taking orders over the web. I know that locally, most of the "sheet metal" shops really do almost nothing but HVAC ducts. I know that you already got your milling machine and don't want to sink money into sheet-metal stuff, but I think there would be a real market for custom sheet metal stuff in the same style as frontpanelexpress and expresspcb. You'd definitely have to sink several thousand dollars in tools and (particularly) punches/dies but at least to me this would be far more satisfying than spending hours milling boxes out of ingots. (How many have you done? Gotta be dull. Of course if you're doing this on ingots that you melted scrap into, you'd hit the occasional hard chunk and void just to liven things up!)

Tim.

What crystal do you need? Digikey sells most crystals for .60 to 1.50 each
, where did you look to find them costing 12 bucks each? curious.... Jim

1901. Data needed on RF2065 MMIC - similar to MAR-3

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-17 23:48:51 UTC
From: TW <kilocycles**@**yahoo.com>
Message-ID: <m6im12pmnjka7hqt3m8cv34qi3pm6h5beb@4ax.com>
Source record: 13002

I need a datasheet on the RF2065 MMIC, or more specifically, RF2065TR7M. Supposed to be similar to the MAR-3, but I can't prove it. The guy I bought some from tested it as if it were a MAR-3, he says.

I want to use it in the circuit of Fig. 11.14 of EMRFD (U4). Note that the part type designations for the MMICs in that figure are inconsistent with the block diagram of Fig 11.13...U4 should be a MAR-3 or MSA-0385 (I guess), not an MSA-0685

Yes, I've Goggled to the max, did all of the datasheetcatalog.com-type and we-may-have-it-but-you-to-buy-the-info.com-type places, and called and wrote RF Microdevices sales support. No joy. This device must have been either been developed specifically for a US Gov't Tippy-Top Secret, Burn Before Reading project, or was the subject of a massive recall; both pure speculation on my part.

Tnx,

1902. Re: focus group question for new products

Newsgroup: rec.radio.amateur.homebrew

Message-ID: <1142643870.029569.240860@u72g2000cwu.googlegroups.com>
Source record: 13003

Haven't done any yet.

I mean, right now I am still exploring ideas of what I can do with a combined milling/electronics/embedded capability as a one person mail order business.

I think there's plenty, so long as I do sufficient market research while asking stupid questions on homebrew or metalworking.

I am learning that it wouldn't make sense to forge my own ingots. I have thought of
a custom chassis system made of interlocking standard parts milled out of reliable ingots made by someone else. I can elaborate privately.

Ironically, I have a potentially infinite source of cheap AL sheetmetal, that wrecker I mentioned that people mentioned wasn't worth donkey dung for making ingots of. I could explore things there. But I really want to keep the few remaining $ that I have in reserve for elex parts and software tools.

A new version of APRSPoint is released, new features include,

1. Implemented APRS server filter setting,
2. Enabled auto connect for TCP connection,
3. Customization of track line width and style,

and numerous other fixes and enhancements. Please visit
http://www.aprspoint.com for details of this new release and sale.
Thanks.

1904. Interested? Here's your FAQ!

Newsgroup: rec.radio.amateur.homebrew

A necessary preface.....

(It is becoming increasingly difficult to fly the flag for
decency and for civilised behaviour in Radio Hammery. Even
the Usenet newsgroups dedicated to the cause have degenerated
into a hotbed of abusive onslaughts by those who ought to know
better; the Nugatory Numpties who boast of an interest
exceeding 10, 20, 30, 40 or even 50 years and yet who have
proved themselves incapable of even meeting the trivial exam
standards set for 6-year-olds. However, there still exists
the fundamental basis on which Ham Radio is based, and
that will never die. This FAQ ("What Is Ham Radio?") will
be regularly published and will not be shouted or bullied
down. It is important that those of a technical bent, who
are the natural seed-corn of Radio Hammery and who
gravitate towards us to be the real novitiate, can
still find us, (and know that we are still here), their fellows.)

-----ooooo-----

So,.....What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then

operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line

telephone, whilst continuing to regard Ham Radio as a separate technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between a Ham Radio licence and a CB Radio licence. To him, they are sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then tries to classify himself as the equal of the Radio Ham when, in fact, he is nothing of the kind.

Ham Radio is not CB Radio and has no common ground with it! Ham Radio is _THE_ technical pursuit for gentlemen; CB Radio is the operating hobby for those who buy their rigs and equipment off the shelf.

-----ooooo-----

If you are the sort of person who is motivated by a technical interest in how things work; if you took apart malfunctioning clocks, toasters and the like and put them right despite never having seen them working, then a Ham Radio licence is your traditional route! There has never been a shortage of such people, and those who gravitate towards such an interest have always been welcomed into our shacks and their interests fostered. There is not today, nor has there ever been, a need to go out and encourage and press children, children who have never expressed an interest in Ham Radio, to come into our shacks. Such an activity should cause eyebrows to be raised - what normal well-adjusted adults seek the social acquaintance of children?!

-----ooooo-----

Please remember that this FAQ is a _POSITIVE EXHORTATION_ to you to exert yourselves to join our fraternity! (If you find otherwise, then perhaps you are already classing yourself in the mediocre groups of those who are criticised in the FAQ and from whom we _MUST_ dissociate? If so - it's never too late for a re-taxonomisation on your part - there's nothing elitist about us, and we welcome all those who are prepared to put themselves out in order to join our ranks!)

Oh, oops...didn't realize they were a mobile rig! I would think you
might be able to find a suitable schematic for the PLL circuitry by
looking at the data sheets for some of the PLL ICs...such as...

http://www.jameco.com/wcsstore/Jameco/Products/ProdDS/246713MOT.pdf

Have you investigated using a DDS (Direct Digital Synthesizer) with a
PIC to control it?

1906. Return Loss Bridge Accuracy Questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-18 13:09:52 UTC
From: skavanagh72nospam@yahoo.ca
Message-ID: <1142687392.568430.122110@e56g2000cwe.googlegroups.com>
Source record: 13007

I have just built an HF return loss bridge according to the info in "Solid State design for the Radio Amateur". While it works ok, I was hoping for a bit better performance. Clearly the "balun" doesn't have enough inductance to operate well below 10 MHz or so (10 turns bifilar #30 AWG enamelled wire on Amidon T23-43, as specified in the book - twisted pair, which isn't specified one way or the other in the book). This can probably be largely fixed by using a larger ferrite core (T37-43's available in junkbox). I am interested primarily in the 1.8-50 MHz range, though I wouldn't complain if it worked on 2m too.

But even at 30 MHz a reasonably good microwave 50 ohm load gives only about 28 dB apparent return loss...Not bad, but I might have expected a bit more.

And an open and short give about 2 dB different signal levels at 30 MHz. That is with big pads (>20 dB attenuation) on both the signal generator and detector. The detector is an HF receiver with a step attenuator used to maintain a constant S-meter reading.

The circuit is built on a small PC board using construction techniques typical for the UHF or low microwave range (except that the test port connector is an SO-239), and is enclosed in a shielded box. Each of the three 50 ohm resistors is made of two 100 ohm 1206 chip resistors in parallel and measures between 50.0 and 50.3 ohms at DC.

Has anyone with experience with this circuit any suggestions for how to tweak it for best performance ? What accuracy level have you achieved ? Do you know where I might find an error analysis for this circuit ? Or if I am to think about errors myself, does anyone know how to model the balun in SPICE ?

73,
Steve VE3SMA

Mike, have a look at:
http://www.qsl.net/yu1aw/VHFPower.htm

A simple design with MRF317 (28V):
http://hjem.get2net.dk/ole_nykjaer/oz2oe/mrf317/317.html

You may find some of the transistors used to be obsolete

regards,

Willem

My homebrew RLB uses a current balun. Some turns of thin 50 Ohm coax on a ferrite core. The core is from a scrapped Siemens inductor. I have acheived good performance between 0,1 to 200 MHz with this technique. I first tried the twisted pair winding approach but the current balun was far better.

Directivity plays a large part in the accuracy of return-loss
measurements. Do some research on how to determine the directivity of
the bridge. If the directivity is less than 30 dB, the return-loss
accuracy will be impacted substantially.

Interestingly, that's exactly what I did.. I revered engineered the Maxon 3010 and have them working fine. Take a look at http://www.w4fhu.org/maxon-3010.htm The Maxon 4010 looks the same from the outside and it appears they started using them because they were probably cheaper. But the 4010's are crystal controlled and that's where I began. Yup, I DO plan on using a PIC and PLL or DDS. Actually the 3010's have the same chip you referenced at Jamco (As you can see from my webpage, above).. I was hoping to use a more modern chip but they all seem to be in the TTSOP format. Actually, I would love to use the AD9835 DDS but again, it's in this TTSOP format and not conductive to homebrewing. Sure I can solder the chip to a ckt board, but I'm not about to have a cktboard made up for a few copies and then find out I made a mistake because I can't really try it before hand. Sort of a catch-22. I am now starting to think about creating a pc board for just the chip to be able to bring out the leads to make them more available for breadboarding. I like the idea of them being in small packages as it cuts down on stray inductances and so on, so sure I'll use them once I have a proven ckt. Ah, lets see what else I can whine about.. LOL

I don't have the book and haven't used the design. However, the
minute you say "SO-239", all bets are off. You must have used an
adapter to connect your "reasonably good microwave load" to the
SO-239. You measure 28 dB RL, that sounds optimistic to me, other
things considered.

I have a link to a must read paper at:

http://www.k6mhe.com/n7ws/

Note No. 11.

Make particular note of the part, "The Curse of Adapters."

1918. Any receiver IC's?

Bus switches like the FST3125 make very good mixers and quadrature
sampling detectors, as in the SoftRock SDRs.

> W4ZCB

Hi all,

Harold, W4ZCB, has given some "comments" on the H-Mode Mixer that are
REAL and TRUE.
G3SBI has removed the mixer from the stages that are critical on a
receiver and in the CDG2000 project it was demonstrated the IMD due to
passive components like core of coils. The FST3125 fast bus switch has
lowered the conversion loss of the H-Mode Mixer and made the RX front
end "hot", although not reaching the IP3 of +50dBm it still has plenty
of +dBm to give ...around +40dBm!You can permit yourself to add a xtal
filter behind the h-mode mixer and still getting high numbers on IP3.

If you are looking for a low consumption and simple mixer you may go OK
with the classic NE/SA602 and similar ones. BUT ... if you are looking
for high performance you need the H-Mode Mixer in the 3 transformer
G3SBI or the 2 transformer I7SWX configurations.
The H-Mode Mixer has been tested on downconversion (CDG2000, STAR
projects) and also on upconversion projects (I7SWX). For upconversion I
have devised a new squarer using LVDS and test it at IF of 35 to 70 MHz
(and 100MHz) with conversion loss around -5dbm and IP3 between +35 to
+40dBm (3.3V FST3125).
The H-Mode Mixer has been tested for RF input up to 50MHz in RX and
converter to 27-28MHz IF.
At 144MHz it performs like a standard diode db mixer having a conv loss
around -8dB. The input limit is due to the internal gates timing and
unbalancing as the FST3125 may have a bandwidth between 300 to 400MHz.
For those interested I may suggest a visit to JA9TTT web page where he
has reported measurement on both G3SBI and I7SWX versions using the
74AC86 squarer with balance adjustment. The comments are in japanese
but a translator is making the reading understandable :
ja9ttt.homedns.org/. I have posted a copy in my web page
www.qsl.net/i7swx in the subdirectory homebrewing. JA9TTT page permits

to enlarge the spectrum analyzer screen pictures.
I have also developed a 1 transformer double balance
mixer/demodulator/modulator using the FST3125 and 74AC/HC86 squarer
with an IP3 of around +25dBm.
Notes on the H-Mode Mixers and 1T DBM have been reported in RadCom,
G3VA's Technical Topics column.
For those interested on more detailed information I can make available
notes in English and Italian. Please write to my e-mail address:.

ADI makes some very nice VCAs, like the AD603. They are probably the
best IF devices available, now. Racal was using FETs for IF amplifiers
in their military radios when I worked for them a few years ago.

PLLs are better than DDSs, but it can be diificult to make a good one.
A DDS may be used to provide a reference for a PLL, of course, for fine
tuning.

You have the wrong newsgroup(s). This is
rec.radio.amateur.homebrew, a forum for discussing the design,
construction, and troubleshooting of home-built electronic widgets
relating to the amateur radio service.

Nowhere in your missive did I detect anything that would remotely
relate to that topic.

Hi All,

I have just found my small stash of these devices along with the Mot
data book. It isn't clear reading the datasheet if this is capable of
linear, or is only class C.

Any ideas ?

Thanks,

Mark.

If it's in the same family as MHW710-x, modulating the input with a linear signal will produce a linear signal at the output, but keep an eye on the drive level and watch for self-oscillations. The MHW710 has been used in ATV applications, which is AM and often has an FM subcarrier too.

I did some SPICE modelling of an ideal bridge (with resistive detector) and came to the same conclusions....that the higher-than-50 ohm-impedance UHF connector and adapter may be a limiting factor in the performance on a good SMA- or N- connectored load. It has virtually no effect on the difference in level between open and short terminations though.

Tim,

Would the following cover most of my entry level needs for sheet metal fab, for getting sheet metal in small enough shapes for my taig? I'll 'punch' holes by using the mill.

The Eternal Squire

18'' SHEET METAL FABRICATION TOOL KIT CUTTER ROLLER

Description

Cut, form, roll beads, and make perfect flanges with one bench top tool. Saves money and shop space. Comes with 1/4'', 3/8'', and 1/2'' bead mandrels; 1/16'', 1/8'', and 1/4'' flange mandrels; and one 18-1/4'' shearing mandrel.

Perfect for auto body workers: make your own wheel tubs, battery trays, dashboards, fire walls, floor pans, and other sheet metal parts and accessories. (Vise sold separately.)

Sheet metal capacity: 18 gauge

Throat depth: 18-1/4"

Andrew

Actually there is nothing really wrong with a DDS all by itself.
They are capable of very low phase noise. The new AD995x series
have 14 bit D/A's and are therefore VERY clean. They are rated at
up to 400mhz clock, but if you don't use the built in clock multiplier
and provide a 1:1 external clock they have been over clocked to
as high as 600mhz! Running with a clock rate of 10x the desired
output frequency this chip should have VERY low spurs!

Instead of using the DDS as a reference for a PLL, consider using it
AS the divider in a pll. This will give fractional N divide ability
allowing you to tune to the nearest hertz without using dual loops.
The math to calculate the DDS tuning word, might be a bit heavy on
a pic though....

That tools claims 18gauge capacity, and probably is thinking of steel
and could do some operations on thicker aluminum.

Not sure what kind of aluminum sheet you have, but 18gauge aluminum is
a bit wimpy for many electronic enclosures. It's OK for a small
mini-box, but very much less than ideal for anything larger.

That tool you point out is OK for a lot of work, but IMHO you'd also
need a "real" shear and a brake to do any sort of box fabrication. Some
of the bending can be done with a homebrew brake made out of 2x4's and
hinges but you'll get tired of this real quick.

If you think you can cut arbitrary shaped holes in large sheet metal
boxes with a milling machine, you have skills I do not have. But I
think it's more likely that you've never done much sheet metal
fabrication. A mill is not the best tool for cutting holes in sheet
metal (although clamping to sacrificial flat pieces of wood does help.)

Tim.

Not planning on large sheets anyway. But thanks for your comments,
they're helping me abandon overly expensive possibilities.

I'm thinking my best niche would be to custom mill boxes up to 2X2X1
with walls at least 1/4 inch thick, with top panel either 1/4 or 1/8
plate up to 2X2. That's plenty for QRP, subsystems, microcontroller
boxes, and some scientific apps.

If you think it's do-able, don't stop just because I said that I tried it and it didn't work for me :-).

Working sheet metal in a mill or a drill press has caused some, um, near-disasters in many amateur shops. Poor clamping resulting in spinning sheets with sharp edges are the most common but I've personally put one dent in a cement wall with some thick sheet in a belt sander :-).

> I'm thinking my best niche would be to custom mill boxes up to 2X2X1

For sizes that small I think you ought to price out some common aluminum extrusions.

2"x2"x1" is really tiny for any experimenting. Not so bad for a small already-known-quantity project with a tiny tiny circuit board. But too small for most homebrew projects and it just barely accomodates a connector or switch or two on each side. And at that size you're smaller than most existing die-cast and miniboxes. Heck, you're smaller than an altoids box :-).

Or maybe you mean 2feet x 2feet x 1 feet? Even then you might want to see what standard size extrusions are around. Quarter inch walls will make a box that large be pretty heavy (not as heavy as the solid aluminum block that big though! By my calculation that'll be 700 pounds of aluminum as a solid block...)

Take a look at some of your competition:

http://www.globalspec.com/FeaturedProducts/Detail/RoseBoplaEnclosures/Aluminum_Extrusions_Custom_BuildABox/9443/0

I think you could one-up them by making a web tool for design/spec/order submittal. Having a selection of common extrusions to start with and then specifying the customizations (mostly holes!, maybe something about end panels, heck in my wish list I'd put painting and anodizing and lettering), punch in my credit card number, hit "order

now", and a couple days later the UPS guy brings a finished box. Seems feasible and a step beyond "fax us your diagram and we'll send you a quote". expresspcb.com and frontpanelexpress.com show that there is a real market for this sort of stuff, both "professional" and "amateur" customers buy from each.

The goal is not to be cheaper than the mass-producers are, but to offer true value in customization and ease of specifying/ordering.

Tim.

1942. Re: focus group question for new products

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-20 17:16:51 UTC
From: Tim Shoppa <shoppa@trailing-edge.com>

To elaborate a little bit about my typical needs and wants:

NEEDS:

3" x 4" x 5" box. Not too picky if it's die-cast or sheet metal or milled out of ingot. Front cover needs a rectangular hole about 2" x 3/4" to let a LCD show through. A couple of square buttons stick through the front panel. A couple of toggle switches stick through the front panel. A PCB is attached behind the front panel (where all these LCD's and switches are mounted).

Internally maybe a transformer. Two D-sub connectors on the sides, so I need nice D-sub holes.

Back panel has several BNC's and other stuff mounted in D-shape holes. Also a IEC line input connector (rectangular hole).

I'd happily pay $50 and maybe $100 for something like this fabbed in single quantities. I might make 2 or 3 orders a year. I'd expect a web or PC-based tool (for free) to help me specify the order, and a web order form that'd let me submit an order at 3AM on Saturday night when the kids are asleep and I have an hour to spec what I want. I'd expect delivery in a week or so. I'd expect the resulting box to be flawless and everything within tolerance and all the holes to be "clean".

WANTS:

Painted (powder-coated?) or anodized cabinet and/or panels.

Lettering on front/back/sides.

Internal threaded bosses or maybe slots for mounting PCB's and stuff.

These could add another $30-$100 to what I'd pay.

My standards about what I'd be willing to pay have little to do with retail prices of existing boxes or what I could hack out with a file and a nibbler but more to do with what typical prototyping services (expresspcb, frontpanelexpress) charge per job and a perceived value in a really finished custom box.
(And a little bit in the cost of specialty punches. I actually have a couple of D-subs and D cutters that I've picked up over the years.)

Some people will tell you that what I'm willing to pay is too high by a factor of ten. These are not your potential customers (and I don't think you'd ever make money by selling to them. No disrespect, I understand those who don't want to pay any money to have other people do work for them.) At the same time what I'm saying that I'm willing to

pay is a fraction (maybe 1/4 or 1/8th) what a local machine shop would charge for a one-off job. I'm not paying because I'm incapable of doing a shoddy job at putting all these holes in an off-the-shelf box, I'm paying because I want a really professionally customized box with nice holes made using punches I don't already own :-).

Tim.

What is the IP3 of a typical dual gate MOSFET mixer?
One can also use HC4066 or 4053 as the switching element at lower freqs.

For radio control on 6 meters using PPM -- what is the amount of
frequency shift, and which direction is it (please don't just say
'positive' or 'negative' -- I need to know which direction is 'pulse'
and which direction is 'not pulse').

Yes, I know there's no standard -- what do manufacturer's do these days?

Thanks in advance.

http://www.nobugs.org/engineer/uav/futaba-rx.html and
http://users.belgacom.net/TX2TX/tx2tx/english/tx2txgb1.htm may be of
some assistance, or at least there will be some pretty pictures.

Positive shift means that the frequency increases during a pulse, and
negative means it decreases. I don't think the exact amount of the
frequency change really matters, but I think it's normally around 1.5
KHz to 2.5 KHz.

Or, to make it really simple, for positive shift, `pulse' is about 2
KHz higher than `not pulse', and reverse it for negative shift. And
modern 6m stuff is positive shift.

| Yes, I know there's no standard -- what do manufacturer's do these days?

From http://www.fmadirect.com/detail.htm?item=1739&section=1 --

SPECIAL NOTE CONCERNING HAM BAND TRANSMITTERS: All current
transmitters use positive shift modulation. When you order for current
transmitters, your invoice will list the purchased item as 805FM50V2FJ
or 805FM53V2FJ. This receiver will work with all recently manufactured
transmitters. If you have an ACE transmitter or an old Futaba (prior
to around 1990), you will require an ACE version. Your invoice will
list the 805FM50V2ACE or 805FM53V2ACE. Please be advised, it is
unclear when Futaba changed from negative to positive shift
modulation. Unfortunately, unless you have access to test equipment,
you may not know if your old Futaba requires negative or positive
shift.

... so it looks like there IS a standard now, at least on the six
meter band stuff. I've heard some say that this isn't true, that
brand X 6m RX didn't workt with brand Y 6m TX, but details were never
really given.

That was useful, but I forgot to ask:

Is the space (no pulse) frequency the nominal frequency, or is it (more sensibly IMHO) 1/2 the shift below -- or at least _some_ amount below the nominal?

If I were designing such a rig I would have the space frequency (off, no pulse, whatever) be 1/2 of the shift _below_ the nominal frequency, and the mark frequency be 1/2 of the shift _above_. I may shade the space frequency to be a bit closer to the nominal frequency to balance out the spectrum, but I doubt that I'd stick it right onto the nominal frequency.

Thanks again.

The shift for the FM (frequency shift keying) is up to +1500 and -1500
about the nominal frequency. This is true for 72 MHz or 50 MHz. This is
used on 53 MHz but is not mandated on this band since the channels are
100 KHz wide.

Thanks Dan. It has to be fairly close in to meet the spectral
requirements, of course -- I just didn't know what the relationship was
between nominal and reality.

You got my curiosity up so I dragged in the ol' service monitor to see
what my 9C was doing. All of the pix were with the freq error meter on
the 1.5KHz range and the scope scale was on the +/-1.5KHz range.

The first was using a FP-TP-FM module on 08 (50.960MHz):

http://www.mindspring.com/~sbhopper/FP-TP-FM_08.jpg

Modulation is +/-1500Hz. The freq error meter is showing about 1KHz
low, but I am assuming it is the service monitor adjusting to the
non-symetrical deviation.

The second pic is with a FT-TP-FM module on 60 (72.990MHz):

http://www.mindspring.com/~sbhopper/FP-TP-FM_60.jpg

Inverted from the 6 meter.

The third pic is with the TP-FSM syntesized module set to channel 60:

http://www.mindspring.com/~sbhopper/TP-FSM_60.jpg

Same as the crystal module except the modulation is just a tad lower.

That pretty much says it all. I guessed that +/-1500 was the number to
shoot for -- apparently your TX (Futaba?) agrees with me.

1957. Re: mixer: DBM or dual gate mosfet?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-21 09:41:49 UTC
From: "Giancarlo Gian Moda, I7SWX" <i7swx@yahoo.com>
Message-ID: <1142934109.266286.184930@e56g2000cwe.googlegroups.com>
Source record: 12958

What is the IP3 of a typical dual gate MOSFET mixer?
One can also use HC4066 or 4053 as the switching element at lower freqs.

JJ

I really do not know what is the IP3 of a DG Mosfet as I never have seen any value reported. I hope some readers may have data on this. Certainly we have to look at IIP3 and OIP3 as the DGM mixer may have high conversion gain 15-20dB and is somewhat limited in dynamic range. Maybe it could have an OIP3 around +5dBm equivalent to an IIP3 of -10 to -20dBm .... more or less similar to the NE602.
The DGM mixer was a common mixer in the first series of transistorized RTX with valves PA (FT101Z, TS820 etc). The DGM has a good square law, better than JFET.

74HC4066 is OK at low frequency conversion but it has a haigh conversion loss, around 8-10dB and so associated noise figure.

Today the switched mixer should use fast bus switches like the FST3125 family when looking at high performance mixers. The examples are the CDG 2000 and STAR (Pic-A-Star) projects with IP3 around +40dBm and +36dBm, where the H-Mode Mixer with FST3125 is used.

With 2kHz shifts I'm not sure that this is particularly relevant. Most of the receivers probably have bandwidths of 10kHz or more.

Ideally the center frequency would fall in the center of the passband of the receiver, following your "1/2 the shift below" if the center frequency were truly accurately calibrated. And the receiver bandwidth would be simlar to the FSK spacing. But things have always been much looser than this.

1kc at 50MHz is 20 ppm, and 30 or 40 years ago when I did 6M remote control I'm pretty sure that most of the crystals would've truly struggled to meet this spec. Some of the transmitters used LC circuits for tuning (I am not kidding!) and receive bandwidths were as wide as 100kHz or more. But that kind of slop was going away as the tube transmitters disappeared :-).

Of course the Gonset portable sets (transmitter and regen receiver both tuned only by LC's) set truly abysmal standards for stabilities and bandwidths. Maybe I'm being too pessimistic in extrapolating their specs to today!

Tim.

Current spec is 20kHz channels, so you have to be better than that.

You are correct that I should expect significant offsets, however -- I
should have been thinking in those terms.

Current spec is _10_ KHz channels. Sure, our (72 MHz) channels are 20
KHz apart, but that's because there's channels for other things
(pagers, industrial R/C, wireless microphones) in between our
channels.

The hazelnuts (or something) are blooming in Oregon, and I'm getting the
early spring allergies.

I had my head stuck in the 6m band, which gives exclusive 20kHz
channels. Yes, 72MHz RC is 10kHz.

I think I need to start tattooing this to my forearms.

Source record: 12966

Allison,
I got the RF2065s as substitutes for the MAR-3/MSA-0385, so that's my problem. I was able to actually get some real MAR-6s, but I need a couple of the MAR-3 or substitutes. Not a bad deal on the RF2065s; 25 of them for $9.95 plus a little for shipping. I needed the data sheet just to convince myself that they'll really work.

I have another problem...now I can't find the ten MAR-6s that I bought earlier! Creeping old age, or something I guess! Unfortunately, they were shipped in a plain white business envelope, and they could very well be hiding in plain sight.

I like your point on the discrete transistor substitution as well. I'll keep that in mind. I have plenty of room on the board, as I'm building only the transmitter and PA chain (for 21 MHz), not the VFO and receiver as shown in the figure.

Thanks,
Ted

Source record: 12969

There are two transmission lines in cascade plus a load impedance.

The first line can be considered to be the main line from the
transmitter.

The second line can be considered to be an impedance matching
transformer between the first line and the antenna.

What is the impedance and length of line in the transformer if the
antenna feedpoint impedance is not purely resistive?

What are the input impedances of the two lines, R+jX ?

What percentage of transmitter power is dissipated in the two lines?
What is the overall power efficiency?

The answers can be found in new program TWOLINES.

SWR is not involved.

Download program TWOLINES from website below in a few seconds and run
immediately.

Source record: 12972

Hi,
I am using a couple of 45MHz crystal filters in my first IF amp.
Has anyone any experience of using these, and give me any advice on
problems they encountered.
I think I have a problem with screening, as they require 700 Ohms
termination resisistance.

When the manufacturers spec a termination resistance, do the filters
themselves look like say 700 Ohms, or do I need to set this externally with
a resistance?

Best regards,
John.

The filters -do not- look like 700 ohm, at least not in the stopband.
Unless a filter has a dissipative loss, the only way it can attenuate
is by reflecting out-of-band signal(s). To do this, it must be highly
mismatched.

The termination impedance is what the filter needs to see to perform
as specified. You must set this either with a resistance and/or an
amplifier designed to present this impedance to the filter.

Thanks for the help so far.
So, I was hoping to make this a good 50 Ohms input match. Looking at the
Philips datasheet for the BF998, for the agc and cross mod test, they show
a fully biased Mosfet, and an ac coupled 50 Ohm resistor across the input.
the input is from a 50 Ohm sig gen.

So does this mean if I set the gate resistance to say 2K, and ac couple a
50 Ohm input resistance, is that better? If so why?

Best regards,
John.

It means that the source impedance of the amplifier driving the filter,
as well as the input impedance of the amplifier following need to be
700 ohms, resistive. Get this wrong and the filter shape will be off.

I may have an interested party, but can list it on e-Bay if this falls through. I'd like to get some idea of where to start.

Yes O.S. can be difficult. Unless you try to call around the local time
they open, forget getting through via telephone. They are a small
operation.

Been there done that for me also.

Yes, I think you have more experience than me, and I suppose I was being pedantic -- but they do want good termination on both ends.

I forgot to add the part that would always happen in my lab: make sure to do a few sweeps, because no matter what my design looks like on paper I always get it wrong the first few times.

If you have all the parts, I'd be interested in them all. I have lots
of dials, but would like to recreate the HBR receiver I built in the
early 60's.

As for the dial, expect about 30-50 dollars. You might do better, but
most fall in that range.

Earlier this month, I ordered on a Sunday and the goods arrived the
following Sunday, in the hands of a neighbor, to whom they had been
misdelivered. When I ran the UPS tracking number, I found that he had
received the box on Wednesday. So, apparently OSE had shipped the first
business day after receiving the order. Ya never know.

1984. 45 MHz IF breakthrough

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-23 07:50:41 UTC
From: John Wilkinson <john.wilkinson@philips.com>
Message-ID: <1jimvb5qzpfuz.eqwrplvmo554$.dlg@40tude.net>
Source record: 12985

Hi,
OK I have a 45MHz crystal filter for my first IF.
The first LO ranges from 45-75MHz.
To test I am using a 45.455MHz LO, which is a pll design.
When I connect up the LO to the mixer, with no input signal I get a -80dBm level out of my IF stage!!
The PLL is clocked off 1MHz ref divided down to 5KHz. The 1MHz ref is a TTL signal. Could this be the cause of the problem, and if so how do I get around it?

Thanks,
John.

Hi John:
terminations are an integral part of a filter design. there are a few
usual or widespread impedances in use. actually the impedance has a
marked effect on the filter's bandwidth, more than on shape. the
narrower the filter, the lower the impedance.
much more critical is the screening problem: the filters's cases must
be very well grounded! any leakage here goes around the filter.it's not
enough to solder to ground the relevant lead: you have to add a strap
from the case to ground.

-80 dBm at the IF output sounds pretty good. Are you using a
high gain, wide bandwidth IF amplifier? How good is the stopband
rejection of your IF filter? Two pole roofing filters are often
not much better than -20 to -25dB.

What kind of mixer are you using? A well balanced or double-balanced
mixer will help to keep the local oscillator signal out of the IF.

PLL oscillators can be very noisy, but it would take a very poor
design to produce strong spurious signals at +/- several hundred
kHz. Designing a PLL from scratch is not easy unless you have a
spectrum analyser or a good receiver that covers the VCO frequency
+/- a few MHz. Pay careful attention to grounding and screening,
especially around the VCO and loop filter. You must keep those
nasty TTL square waves away from the VCO. Make sure the DC supply
to the VCO and loop filter is very clean and stable.

The singly balanced mixer using 2 DG MOSFETs seem to be better still.
Does it have a higher IP3 than a single ended mixer?

Why use a AD831 if the noise figure is 10dB?

Hi,

Just a few days left on some good stuff cheap! Low starting bids, no minimums, good feedback rating. A super chance to stock the parts bin and save space in the landfills for more deserving stuff.

Take a look at these auctions: http://search.ebay.com/_W0QQsassZkk1w2000.

Lots of old and new parts, caps, resistors, pots, coils, meters, crystals and more. Low starting bids and good feedback rating.

Thanks for looking,

Jim, KK1W

Source record: 12992

I'm hoping I can get some ideas and guidance here...

Here's the story so far:
I'm trying to build a Narrow Band (and/or Super Narrow Band) FM Receiver, targetted primarily at frequencies around 75MHz (The band our Fire service operates on here).
Now, I know the MC16136 IC would be almost perfect, and I can find many circuit diagrams for it, as well as for the famous TDA7000 (and children of the TDA7000), however, I can't find a reliable source in New Zealand for these two ICs.

So what I am looking for is, a circuit diagram for a NFM receiver that uses current production chips, that I can get my hands on. (I am considered building a few of these, but not enough that I can order these chips from overseas).

If anyone has any ideas, or places I can try, etc I would very much appreciate the input.

I do have some electronic skills, and can build basic single layer PCBs, so I'm not a total novice.

Obviously what-ever I eventually come up with, I will be posting such circuit diagrams on the Internet, share and enjoy, etc.\

Thanks,

Nick

Ok, I like to try the AD831.
When is dual supply better than single ended?
There must be a socket to fit the package but is it all right to solder
tiny leads to it for prototyping?

SolderSmoke!
A SHOW FOR ELECTRONICS HOMEBREWERS!

http://www.ourmedia.org/node/191977

Topics discussed in SolderSmoke #18:

-- Designing class AB amps with LT Spice
-- Solar Max and aurora in New York (1969)
-- Fishing Pole rotateable dipoles
-- Fixing HW-8 with field expedient soldering iron
-- Hack-A-Day
-- Homebrew MP-3 player
-- Shacktopus
-- Work benches
-- Mars Orbiter, Water on Saturn's moon
-- Video from Alps http://www.ourmedia.org/user/36170
-- MAILBAG: G4GOY, NT7S, Mark in NJ, Michael in
Australia, RSGB

Listen at: http://www.ourmedia.org/node/191977

Background:
Tired of listening to Led Zepplin or NPR on your
I-Pod? Wouldn't you like to be able to carry with
you the kinds of ham radio conversations that you
listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in
London, England meet regularly on the ECHOLINK system
to discuss their homebrew radio projects. We are
making them available as PODCASTS.

You can subscribe to the program, have them downloaded
to your MP-3 player, and listen to them at your
convenience. To subscribe, just cut and paste this URL
into your I-poder (or similar) software. (There have
been some problems with this subscription URL.)

http://www.ourmedia.org/mediarss/user/36170

If you don't have an MP3 player you can just go to the
site below and listen to the latest program (and
earlier editions) using the audio software on your
computer.

http://www.ourmedia.org/node/191977

Here's the homepage for our show. All our programs are available here. There are also some videos, a blog and links to some of the sites and documents we've been discussing:
http://www.ourmedia.org/user/36170

We hope you enjoy the program. Please send us feedback.

Hi all,

Allison has given important information on mixers data.

His comments are very usefull.

I would like to underscore the last note:

> All of that is good but unless the post mixer amp, IF and filters
following it are up to the task and well matched the results can be
very disappointing. When going to that level of performance one
needs to look at the recieving system and examine carefully.

It is right to relook at a receiver design when selecting a high
performance mixer. The limiting problems will show up in other stages
as the improuvements may not be very detectable.... amplifiers,
filters, l.o. phase noise...

Well one need to start from somewhere to improuve a receiver. If the
non mixer stages have a maximum IP3 of around +15dBm, certainly a
+35/40dBm mixer may not make much of a difference, unless it is
replacing a NE602. In this case you may use the I7SWX 1 transformer
double balanced mixer using the FST3125 (half of an H-Mode mixer) with
an IP3 of +25dBm.

As an example, I defined with afriend of mine a mod on the Elekraft K2.
The 1st mixer (TUF) was replaced by an I7SWX 2T H-Mode Mixer followed
by a 10kHz BW 2 xtal roofing filter . Two tones at 7.050 and 7.070 MHz

IP3 Results of the K2 were:

Original mixer: +15dBm
with H-Mode Mixer: +27dBm

as you may see these are important differences. The actual limiting
stage is the original post mixer amplifier.

From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <9uidnbvxuaV947jZRVnyrg@bt.com>
Source record: 12898

A loading coil inserted in an antenna, or a close-wound helical, can
be considered to be a transmission line. It behaves as such.

From a coil's physical dimensions, program TRANCOIL calculates the
line's distributed Inductance, Capacitance and Resistance including
radiation resistance.

Also Characteristic Impedance, Phase-shift, Propagation Velocity and
Attenuation.

Should the coil be used as an antenna, the resonant frequencies are
found, also the feedpoint impedance, R+jX, versus test frequency.

Input data can be varied via the keyboard to observe how the coil
performs versus length, diameter, number of turns and frequency.

The program is both educational and practical.

Download program TRANCOIL in a few seconds from website below and run
immediately.

Gail (KB9MII) and I (WX6RST) are going up the Alcan to Wasilla by way of Seattle in June. Can anybody shed light on whether there is any activity along this route, especially on 2 meters. We can jury-rig anything from 80 meters to 1 Gig if we have to, but 2 would work exceptionally well.

John,
How about a miniature stereo phono plug? These have 2 signal circuits plus a ground. They're common, they're available in many PCB configurations, and they're cheap.

Dale,

I believe you posted an e-mail and a link to QRP-L a while back to show your receiver. Should have said this before but better late than never. Nice job.

If I remember correctly you used a basic 160M receiver with multiple front end convertors. Also I believe you used blue backlighting?

Hi Don,
Thanks for the kind words. The receiver is based on W7ZOI's Progressive RX
from the late 80's. To Wes's excellent design I added,
S meter
AM detection
LM386 for loudspeaker w/ tone control
audio notch filter
Homebrew 5/2.5/.5 xtal filters
fast/slow/off AGC

80M RX with xtal controlled converters for 160/49/40/20/15/10ABC
The VFO drifts a little over 150Hz in the 1st 5 minutes then settles down to
+/- 20Hz in a 5 minute period. Wonderful sound and gets more use than the
PRO II
73,

Dale W4OP

Unless you have to move the IF osc around, why not use a crystal?
With a 5 KHz PLL reference, you might have some sidebands from this.
What is the cutoff of the loop filter?

Hi JJ,

the note on the 1T DBM was reported in RadCom, Technical Topics column, June 2004.

I asked a friend to insert all mixer infos in my web page www.qsl.net/i7swx but I do not know when he will be able to do it. In my web page in homebrewing you my read the experiences and measuremnts done by JA9TTT on both versions (3T & 2T) of the H-Mode Mixer. This is a software package translation from japanese but it is understandable. You will be able to see Spectrum Analyzer measurents too.

If you send me (callsignatyahoo.com) your e-mail address I can send you the complete 1T DBM note in english (more stuff than in TT).

A NOTE for ALLISON ... I see you have been fiddling with DEC stuff. Were you working for DEC or a customer? I was with DEC for a quarter of a century ...hi

Well Dale it looks very nice and obviously works well too. I thought I remembered you saying the Progressive Receiver. I am glad I had a chance to compliment you.

Since the subject was the Eddiestone dial I expect that was probably a chore to install. I usually build homebrew dial chord and drum mechanisms and more recently use the flange type Jackson Brothers and Oren Elliot drives. I just figured out a way to make custom dial plates. Probably an old idea but new to me.

I just finished a 40M receiver for a SSB transceiver. I thought about using a small blank CD for the dial plate. What I ended up doing was getting a piece of brass sheet from ACE Hardware and using a 2 1/4" hole saw (my chassis panel is 3") I cut a round disc. I had a small amount of deburring to do but the brass is way tougher than aluminum and a simple file removed the burrs. The 3/8" drill bit also provided a true center for the dial plate. I polished it with super fine auto rubbing compound. I ended up with a nice dial plate.

I need to mount it to a small shaft section of a vernier capacitor from Ocean State Electronics. I took a shaft coupler, the type with removable couplings on both sides, and using very tiny scews mounted this removable portion of the coupling to the plate.

Its hard to describe. But I am pleased with myself as I a mechanically weak.

This is a good method for making custom dial plates. I had to use a good chord type drill as my cordless was getting warm. I also mounted the plate for drilling using two wood screws and fastening the uncut plate to a scrap 2 x 4 by drilling holes slightly above and below my cut.

Now I gotta figure out how to mark the plate. Well maybe I will catch you on the air sometime Dale.

Problem with a phono-plug and a clock signal is that you will get reflection back -- probably much better off with a BNC or SMA connector.

The author said it was RS-485. This is a 2-wire differential signalling system. He also wants to use a shield. Hence the need for 3 circuits. I doubt that reflections will play any part in the performance, especially considering that he's using twisted-pair for the signals. This is how CAT5 RS-485 distribution works.

Besides, he's talking about a1 MHz presumably steady-state square-wave clock and presumably short board-to-board connection lengths.

2011. Info needed on Motorola 2 tube RF deck

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-27 02:17:17 UTC
From: Ken <VHFNUT@whoknows.net>
Message-ID: <DZOdnQg-Ut621rrZRVn-uQ@adelphia.com>
Source record: 12912

I have a Motorola amplifier from a working remote base. The only number I can find TLD6612A on the PA deck. It is a two tube, conduction cooled amplifier that was operating on 161 mhz. The tubes are 65-82282D02 (Eimac 8560AS I am told is the same tube). I would like to know if anyone has converted one of these PAs to 2 meter SSB and any hints of how to do so. I don't have the manual for the remote base or the PA.

Please reply to the group.

Thanks guys,
Ken

This group has the most complete collection of modifications, usage tips, links to related websites, documentation, and photos along with a user survey and a message forum (4000+ messages archived) to help you get the most
fun and DX out of your Realistic / Radio Shack DX-394, DX394, DX 394.

Over 90 mods and tips now listed plus a dozen on the To Do or Wish List. More mods than for any other general coverage receiver! Thoroughly documented with a Master Index. If you like to tinker with radios, I know of no other recent model that lends itself to as much fun in this arena as the DX-394. Great platform for learning radio-electronics. Always 1 or more FA on eBay.

Active & friendly user community now with over 1000 members. Some members are
keen short wave listeners; others are into AM DXing and a few enjoy long wave. Many experiment with antennas and some are ardent modifiers - customising and souping up the rig as hot rodders would do with cars. You'll find lots to interest you and help get the most out of your radio.

HI,
Yes this is a differential signale, so needs 2 connections plus ground for the shield.

I have looked for these stereo phono plugs, but to no avail, any idea who stocks them, RS/Farnell numbers.

Thanks,
John.

John,

Over here we'd just run down to the nearest Radio Shack store, or if we had to mail-order them we'd go to Digikey (www.digikey.com) or Mouser www.mouser.com). Here is a link to a digikey catalog page that shows the different types they carry:
http://dkc3.digikey.com/PDF/T061/0304.pdf

Also, here is a link to a Digikey search page from which you can narrow your search down to a specific type and stock number:
http://www.digikey.com/scripts/DkSearch/dksus.dll?Criteria?Ref=4998&Site=US&Cat=32440884

If you follow the above link to a specific connector, you'll eventually get to a page that has the manufacturer's web sites and datasheet information. This might help you at least pick a connector type, then go to the manufacturer's web page and find out who stocks the part in your area.

Joe

Hi

I would use a USB connector and cable. These contain two (possibly three) twisted pair with a shield around them. They are controlled to 93 ohms differential impedance, and do not have significant reflections below 1 Ghz when terminated properly. They are cheap and plentiful, and available in a variety of sizes for PCB mount.

Mouser sells a good assortment--I usually go for the 'B' size for PCBs. I use these for an RF differential probe I designed, with good results.

There are also lines of shielded telephone connectors and cable available. For a 1 Mhz clock these would do well, and do not have as low an impedance, which might be easier for your 485 drivers to work into.

Regards,
Glenn

(Let's try again with the URL hopefully corrected - I don't understand how they got corrupted in distribution - looks alright leaving here and on screen but the actual properties show an extra character)

This group has the most complete collection of modifications, usage tips, links to related websites, documentation, and photos along with a user survey and a message forum (4000+ messages archived) to help you get the most fun and DX out of your Realistic / Radio Shack DX-394, DX394, DX 394.

Over 90 mods and tips now listed plus a dozen on the To Do or Wish List. More mods than for any other general coverage receiver! Thoroughly documented with a Master Index. If you like to tinker with radios, I know of no other recent model that lends itself to as much fun in this arena as the DX-394. Great platform for learning radio-electronics. Always 1 or more FA on eBay.

Active & friendly user community now with over 1000 members. Some members are keen short wave listeners; others are into AM DXing and a few enjoy long wave. Many experiment with antennas and some are ardent modifiers - customising and souping up the rig as hot rodders would do with cars. You'll find lots to interest you and help get the most out of your radio.

Hi Allison,

thanks for the update. I was with DEC from 69 till 93 ... serial #
7133 ...hi

My #1 machine (FS) was PDP9 , also PDP series and alittle bit PDP11 and
15... I applied several mods in the field that made crazy many people
in DEC ... but we were working in he field without spare parts ...I
replaced transistros, transformers (core mem drivers) ICs...etc.... The
day I was told not to do on my way...I saw something wrong.. the
largest PDP9 installation in the world (I3) went into smoke ... then my
boss changed mind...hiu

Glad you got your 6m SSB rig working nicely.

BTW if you are in Mass and you do hear my good friend Art, K1GBX, on 6
meters please say hallo for me... he will get crazy...hi I also have
some other good friends from the old DEC Ham club and others...

2024. D104 distortion

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-27 15:50:38 UTC
From: pdrunen@aol.com
Message-ID: <1143474638.836258.56200@v46g2000cwv.googlegroups.com>
Source record: 12925

Hi All,

I picked up a D104 Silver Eagle and was observing the output of my scope.

I see that it appears to clip out the negative peaks which makes the on the air sound distorted. I checked the audio with the output terminated into 100K and also tried various settings and battery voltage levels.

Any thoughts?

de KJ4UO

John,

When working toward the best ultimate attenuation (in the stop band) for filters and high gain IF stages in general, you also need to pay attention to ground currents for the input and output of the filter as well as (applying the same principles to) the related stages-- And the stages well before and after the filter.

I often say; "A grounds a ground the world around.", but this is a play on words with the old saying "a pound's a pound the world around" as well as a tongue-in-cheek (reverse) reference (more specifically irony) to the fact that an RF ground can be elusive if not properly understood. [[in other words, an RF ground is NOT necessarily an RF ground...or the concept of "any ground in a storm" will NOT "do" for RF]]

Make it so the ground current path for the input has as little in common with the ground current path for the output. DO NOT just make a ground plane and expect it to be better the bigger and more complete it is. Consider ground current exactly as you do the "real" signal path. If the filter has only one ground pin, make separate ground planes for the input and output and have them connect __right at__ the pin...and ONLY _AT_ the pin --- AND from opposite directions. If there are two pins, cut the ground plane so the two pins have NO connection directly between, but only via mass quantities of other routes, via far distant lands from the filter. You must force the ground currents to go where the schematic says they should go as thought you can not use the ground symbol. Any small amount of

conductor which has both the input and output ground return currents is a source of coupling. Sometimes MAKING CUTS in a ground plane improves spurious responses---been there--done that.

Hope that is clear. However, if the ultimate of the filter is only 50 dB, you're screwed. You need to do what others do, use two or more filters separated by stages, space and, of course, ground.

ALSO, random capacitive coupling (technically referred to as "spray" by those in the profession) must be reduced by physical separation and shields. AND don't allow a shields to provide a ground current path that is not following the above ground recommendations.

Hope this helps

73, Steve, K9DCI

Another thought - the Silver Eagle is an amplified D-104.
Bypass the amp and see what you get.
A friend had a bad amp in the base of the D-104

Which of these mods do you think increase sensitivity at the expense of
dynamic range?

> Remember some of these mods are made by amateurs

Many of whom are electronics professionals. That's not to say that novices
at electronics do not carry out some mods. One of the virtues of the DX-394
is that it can be readily modified and doing so is a great educational
activity for someone getting into radio and electronics.

> The factory engineers designed the sensitivity for very good reasons

And made some mistakes in other areas, e.g., decoupling around the IF
filters, AGC time constant for SSB (factory corrected in the revised
versions), and some design trade-offs or decisions that owners want to
correct. That is true of every product.

They're also prone to be affected by rf. I had a coiled cord on mine
and had to run a direct wire inside the cord from the base to the mic
plug to get rid of the rf.

Dave, try a Google search using the brand and model. I was able to get the service manual for the old (70's) CDR TR-44 rotator that way. It's amazing what's out there.

I refer you to the Elecraft page
http://www.elecraft.com/K2_perf.htm

Sez
MDS = Minimum Discernible Signal (3db increase above noise floor). Larger
negative numbers are generally better, but too much sensitivity can reduce
strong signal dynamic range and Ip3. Pre-Amp On MDS numbers of -130 dBm or
more are more than adequate for most HF band operating, since band noise is
typically above this number. (Lower frequencies need less MDS (more +number)
due to an increase in atmospheric noise.)

Have a quantity of Radio Communications Service Manuals, both Commercial & Amateur that I have rescued from the Dumpster. Most ot them are in Like New Condition.

Please check my site: www.rodemi.com for what is available. I am updating the site as time allows.
I recently retired from the Commercial 2-way radio business and have a "goal" to clean up the Garage & Basement.

Thanks for looking....Norm VE3CZI

Problem is, many times those reasons have more to do with cost than
with performance.

I have no dispute with that. Rather with your first comment:

>>> Just FYI: I see a lot of these mods to increase sensitivity -- resulting
>>> in trashing the dynamic range
>>
>>
>> Which of these mods do you think increase sensitivity at the expense of
>> dynamic range?

You did not answer the question. The answer may well be 'none'. I'm not
aware of any aimed at increased sensitivity, unless adding an amplified
preselector counts as a mod. And that could arguably be for improved dynamic
range and sensitivity by improving front-end selectivity and noise figure.
Most regard the DX-394 as a very sensitive receiver that is outperformed in
that spec by few others. But itcould do with improved overload threshold and
IP3.

Methinks you might be trashing imagined mods rather than the ones
well-documented in the user group.

Tom

The DX-394 is a scanning receiver, reviews have described its user interface
as reflecting a scanner heritage, it has been a topic in all the newsgroups
to which I posted the notice, and similar notices have been crossposted a
few times in all these newsgroups informing potentially interested parties
about http://groups.yahoo.com/group/RADIOSHACKDX394/, without objection.

Are there any other newsgroups for which it would be relevant? The ones I
posted to are:
rec.radio.shortwave, alt.radio.scanner, alt.radio.scanner.uk,
rec.radio.amateur.equipment, rec.radio.amateur.homebrew

Thanks Allison for your info. Looks like another one for the trash can. I figured that the tubes which I figured would do as much as 4CX250s would get me to 300-500 watts SSB. Oh well we can't get lucky every time.
73,
Ken, WS4V

If you want to be popular work 6M as you travel. You should have some Es openings in June and you will be travelling through rare grid squares. You will have lots of pileups and lots of fun. Have a grid square map and announce your square when calliing CQ. It is amazing how much better people hear you whe calling from a grid square that is usually uninhabited.

I envy you - I have travelled in that area and it is amazing countryside and the folks are pretty friendly along the route.

Regards - Roger

There are a lot of historical chips and solutions around on the market and in the litterature. I use the Analog Devices AD8343 mixer, good for DC to 2.5GHz and with a IP3 of 16.5 dBm.

The 602 is now replaced with the 612 but is still an old design.

If you design your mixer (/doubler) with AD8343 and use proper RF transformers from CoilCraft, it just cannot go wrong... (well, Murphy et al of course...)

Cheers

Da / M0DFI

2047. DSP Speaker

> and WHY was it cross-posted to 6 newsgroups??

I was intrigued by that post and joined the group. DX 394 is quite a bit
part of a listening hobby.

The DX 394 scans a slightly different breed of frequencies...or does it?
My Yupiteru MVT 7100 picks up all those same frequencies also, and then
some. Does that mean my Yupi is technically NOT a scanner because I can also
use it as an AM/FM/SW/SSB/Weather/TV audio/
CB/Communications/Marine/Police/Fire/Ambulance radio receiver as well?

Jack

2050. Re: Eddystone dial and custom dial plates

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-28 01:46:56 UTC
From: Ted <kilocycles**@**yahoo.com>
Message-ID: <8h3h22582psr78h3n6iq7q3thdgr628c1d@4ax.com>
Source record: 12849

Don (and Dale, if you're still listening),
I apologize in advance for not snipping this reply, but I want to preserve the whole thread and file it to my Hints and Kinks folder on the hard drive, for that dial mechanism.

Speaking of the Progressive Receiver, I was thinking about building one myself a couple of months ago. At the end of the article in the November '81 QST, Wes shows the math to figure out capacitor values for the VFO. Well, I spreadsheeted that, and I may have found an error. I check for errata on the ARRL site, and didn't find any further references.

Everything checks out perfectly until the last step, where he solves for C3. Wes's example yields C3 = 127.02 X 10E-12 F.

My values show C3= 355 -(1/50 + 1/126.8) quantity to the -1 power, which is 355 - 35.85 or 319.1 pF, not 127.02 pF. Did I mess up with the math?

This is fairly significant to me, because I can see use for this calculation beyond this particular project, never seeming to have the right variable cap on hand. I floated this problem to the local NoGa QRP math gurus, but it turns out I guess we don't have any :) . I didn't really want to put it on qrp_tech.

Dale, I've commented to you previously on your magnificent receiver, and Don, that's a nice idea on the dial plate. One thing you could do is design the markings in a drawing program to fit your brass disk, and then iron on a Press-n-Peel image to the brass, and etch it. Then you could apply a layer of black paint to the disk, and carefully wipe it off until only the etched areas remained with paint. Alternatively, If your image is clear enough (reversed this time), you could simply use that after ironing it on, and spray it with a fixative to protect the toner and the brass. A couple of the guys were doing that for panel legends.

Some of the guys in the homebrew_pcb Yahoo group have built their own CNC milling machines, and the do their PC boards that way. That would be good for this, as well.

72/73 to you both,
Ted KX4OM

It is a LW, MW, SW receiver that scans. Is alt.radio.scanner restricted to
discussion of scanning receivers that can tune only above 30 MHz?

Do a search in alt.radio.scanner:
http://groups.google.com/group/alt.radio.scanner/search?q=DX-394+OR+DX394+or+%22DX+394%22&
start=50&
- 66 threads found, dating from 1996.

>
> It's also NOT amateur equipment any more than it is a scanner,
> and CERTAINLY not 'homebrew'.

Why is the DX-394 NOT amateur equipment (I assume you mean 'amateur radio')?
It tunes the HF ham bands and does a credible job receiving the popular ham
modes on its own and is used with software to receive many digital modes. It
is found in many hamshacks. My first SW receiver was a 5-tube Heathkit AR-3
general coverage radio - it doesn't hold a candle to the DX-394 - but it was
the receiving part of my ham radio station.

I agree that the DX-394 itself is not 'homebrew' but the many mods are of
interest to some homebrewers as have the design discussions carried out in
rec.radio.amateur.homebrew.

When did you become the self-appointed policer of these newsgroups? As far
as I can tell, my original post was in the spirit of guidelines about
cross-posting. Your carrying on with this nonsensical criticism by
cross-posting replies is not.

End of discussion.

Tom

2053. Simplified G2 Regulator for a 4CX250B amplifier

Newsgroup: rec.radio.amateur.homebrew

Source record: 12854

Hi All,

I have been toying with the idea of building a 4CX amp for some while now but keep being put off by the relative complexity of the protection circuitry associated with G2.

I (think) that I have read cover to cover the G3SEK and GW4FRX articles on the subject, and hope that I have ended up with a usable if not simplified version of the work done by G4JZQ.

I am not trying to compete with any of these guys, I am just trying to offer another view on the subject.

Take a peek
http://www.geocities.com/markaren10/RF_amp/Simplified_G2_Regulator.pdf
and let me know your thoughts.

This is about 2 hrs work from "engage brain" to "publish first ideas for comment" so don't be too harsh.

Regards,

Mark.

2054. Need info about pyramid antenna and it's performance

Hi All,

I am a SWL from India and hope to get a ticket soon. I am constructing a simple receiver and i would like to construct a good antenna for my receiver and in future for my transmitter as well. I came across a design in a souvenir released by Hamfest India where an antenna called "Pyramid Antenna" is described. The author gave reference to one design published in Radio Magazibe 1982 by Steve Bauer,DJIUS. I came across another similar design described in http://www.warc.org.uk/clubmag/qsx13.pdf . I would like to know more about this antenna and the experience of using it, about it's performance. My house is near a 11KV power line and my antenna will be less than 15 feet from the above said power line.

Thanks in advance.

Regards
Shan

OK. Have you checked with varying the settings of the 5k pot in the amp section? - have you checked that the battery volatge is correct (ie, measured it?). If that doesnt work, connect your CRO across the mic. capsule and see if its the cause of the problem..... If its the amp, shouldnt be too hard to troubleshoot - even if you shotgun replace EVERY component on the board its a simple job. For schematic, just Google for it - for some reason, I cant copy the link to this reply.

Source record: 12857

What are you trying to do?

TR1 looks like a current limiter for the FET. Why are you doing that?

The source voltage looks like 425 volts, the series resistor 10k 2W,
the shunt regulator threshold 340-350 volts.

that's about 75 volts differential, so the 10k would have about 7.5 mA
of current. If the screen loaded more than 7mA it would fall out of
regulation.

The FET dissipation would be 2.5 watts assuming no negative screen
current.

What holds the screen to ground when the overload opens?

Why is the VDR on the screen side of the screen current meter?

Maximum screen dissipation would be around 21 mA when the screen was at
about 200 volts. Maximum screen current about 40mA.

While I don't know anything about the pyramid antenna, I do think that
I'd want any antenna _MUCH_ farther away from a 11KV power line than
15 feet. That's uncomfortably, even dangerously close.

Best of luck on getting your ticket.

Regardless of the antenna, you don't EVER want to place an antenna anywhere near a power line! Not only is this a safety hazard (a still wind could blow your antenna into the line), but you will experience a large amount of noise from the line.

My general advice:

1) Keep antennas at least 100 feet away from power lines.
2) If you can't create a horizontal antenna that obeys the above rule, consider creating a vertical.

Questions so our group can give you specific advice:

1) Do you live in a crowded city, or a wide open rural area, in the suburbs?
2) How highly regulated is the community in which you live?
3) Would your nieghbors allow the extension of your antenna to thier property?
4) Are there any common features near your house (ravine, fence, tree, bridge, railroad) that would give you extra possibilities for space or mounting.

Good Luck,

The Eternal Squire

Hi Tom,

"I have been toying with the idea of building a 4CX amp for some while now but keep being put off by the relative complexity of the protection circuitry associated with G2"

Basically, just simplification. See http://www.ifwtech.co.uk/g3sek/boards/tetrode/tetrode-manual.pdf for the whole of Ian's manual (chosen starting point)

There is a bunch more protection stuff on the base of the tube, I forgot to mention this in the posting. I should have also said that the starting point for the review should be topological.

I will look at your detailed comments when I wake up (it's 3am :).

Thanks very much for taking a look.

Regards,

Mark.

>If you design your mixer (/doubler) with AD8343 and use proper RF
transformers from CoilCraft, it just cannot go wrong... (well, Murphy
et
al of course...)

>Da / M0DFI

Hi Dan,

Yes the AD8343 is an interesting mixer... but for me it may be too
noisy (10dB). THe IP3 is certainly much better (+15dBm) than the
602/612 (-15dBm), but this one has a lower NF of 5dB.
If you build my 1 homebrew transformer (50c) FST2125 DBM you do get am
IP3 of +25dBm NF 5dB ... adding a post mixer 10dB LNA you probably get
a 3dB NF.
Certainly you have to select the most valid mixer for the specific
project as always we have to compromise and give priority to one of the
many parameters.

2064. Heterodyne Mixer for FFT Spectrum Analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-28 22:24:20 UTC
From: Ted <kilocycles**@**yahoo.com>
Message-ID: <qtcj221vj9cppdmslrkfmgfjt2l5fj2rtf@4ax.com>
Source record: 12865

I have a PC-based oscilloscope/spectrum analyzer that covers up to 16 MFz. I can see the second harmonic of a 40 meter signal, but that's about the maximum extent of its utility. I recently came across an idea where a set of local oscillators and a mixer could be used to extend the range, with the 0 to 16 MHz input of the FFT SA being the IF, essentially. I can't recall where I saw that, unfortunately.

I figure I could use 4 or 5 LOs in a shielded compartment, outputs matched for gains, and switch them into the mixer to produce frequency ranges in 16 MHz increments. I have some wideband MAR-8 MMICs that I could use (attenuated) for the RF to make up for the Mixer loss; i.e., deliver the same signal level I currently get at 50 ohms with 0 to 16 MHz signals.

Anyone have any suggestions on this idea? The unit I have is pretty neat, being able to store the o-scope and SA plots digitally, with positionable cursors for readouts of points on the waveforms.

73,
Ted KX4OM

If you are referring to the slide rule dial they are now as rare
as hen's teeth. I had one in the junk box that I found at a flea
market years ago but never used it. I put it up on ebay and was
a bit surprised to get over $100 for it. These dials are prized
by HBR builders! Millen also made a few sliderule dials, one
used a toothed belt to drive the pointer.

Actually if you derive screen voltage with a dropping resistor to a shunt regulator, and set the standing dissipation of the regulator at rated screen dissipation, there is absolutely no other protection required.

All you need to do is have a screen supply that is twice or more the end voltage you need and that simple shunt circuit and the screen can NEVER be over dissipated, even with loss of bias and HV.

The only exception would be a tube that operates with high levels of negative screen current, but that is a very rare amplifier and not likely a situation that could be protected by any system.

Source record: 12870

Thanks for the Schematic link.

The D104 is connected to the Oscope and terminated into a 100K resistor. It is not connected to the radio so RF is out.

The Oscope shows clipping on the negative peaks, the postive peaks are OK.

I tried removing the battery and powering off a power supply where I could vary the voltage to see if the distortion disappeared with voltage, it did not. The affect was a lower audio output.

the best thing to do is to replace the two NPN and see what happens.

Hi All,
Thanks for the posts. I live in Bangalore, a very crowded city. My dad
is a HAM and his call sign is VU3SMX. He is not active on the band
nowadays because of his age, 70 years. I used to help him erect
antennas and we had experience with inverted V antennas. In our
previous QTH we didnt have any problems with the erection of antennas,
because we had ample space.
Regards
Shan

go with the simplest one! something like a dual gate FET: that's going
to ease problems with the local oscillator.
But build it as a separate module on a small PCB, and wire it in. that
way you'll be able to experimwnt later on by replacing the module. that
way you can go from easy and simple to complex and high perfoemance.
for a first it hard to beat the method. i see you're getting too much
info, especially for a newcomer!
stay in touch, I'll try to help you to the limit of my abilities.

guys, bear in mind that the intercept point is primarily a function of the operating quiescent poit. you cam make it high, really high and get superlative mixers, even single ended. i designed one aroun the now defunct VMP4 from Siliconix with an Id of 500mA!!! the damned thing had nearly +50dB IP#. About the same went with the LNA. All in all 24W power dissipated in the front end. How many of us can afford that or need that for the matter?
drop it! what the guy needs is some reasonable value of dynamic range and around 10-12 dB for IP3. he isn't going to build a radio telescope receiver on his first attempt. Be reasonable!
with FET's the thing to ensure is that the operating point is setablished with Vgs set at about half of the pinchoff voltage to ensure maximum dynamic range. a noise figure under 10dB is adequate for HF. it's not the galactic noise that limits your reception!

Source record: 12874

Hi,

I would very much like to hear from anyone who has had any
experience in repairing the HP8443A as I'm looking for a few
pointers, source of spares, etc. I have one in good condition
except for a fault in the ALC/Video Amp (A8) - possibly either the
output or preamp hybrid. Together these items have 52dB of gain
giving +10dBm of output from 100kHz to 110MHz. If I could get
hold of just the spec or internal schematic/block diagram of these
items (5086-7099 [U2] and 5086-7010 [U1]), that would help me to
lash-up substitutes but the correct spares would be real nice as
so would a complete working A8.

TIA - Joe, G3LLV

Maybe one of the transistor's biasing network is at fault. I'll assume the transistors are biased class A, which means the collector voltage (assuming common emitter circuit) should be at about 1/2 of the supply voltage. It sounds like one of them might have the collector voltage running below 1/2 of Vcc. Check the resistor values with an ohmmeter. Transistors are usually the last thing to replace...

Hi Saandy,

I have some russian power FET similar to the VMP4 and probably better
but there is no sense to use them as they are no more in production and
diffcult to purchase in East Europe.

I believe a discussion on Mixers is important particularly for a
newcomer. He must know all the different kind of mixers than he will
have to decide.... it is like talking about small car or motobykes
because it is better run with a bicycle...one should not know about
racing car or motobykes.... he can putchase a byke tha add a little
mosquito engine or pss to a bigger motobyke or a small car later ...
but he will know what he has (he will have to push a lot with his legs
and then see to push less or not at all).... it is like for a portable
RTX were consumption is at premium... you cannot put (probably an
h-mode mixer has you will have to spend 30-50mA plus an amplifier with
other 20mA versus a NE612 that needs 3mA !!! To hell the IP3... one can
use his brain as a DSP...hi

First bypass the amp and see what it does. It may be a bad element.
They will sometimes give funny distortion when they go bad.

Simplest way is to use a double balanced mixer, like a mini circuits
module, and a signal generator for the LO. Works great.

2078. "Fan" capacitors for microwave RF design

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-29 17:16:04 UTC
From: Joel Kolstad <JKolstad71HatesSpam@yahoo.com>
Message-ID: <122lg8eg3830g0d@corp.supernews.com>
Source record: 12879

I'm curious... at microwave frequencies often the required capacitance for some matching or tuning network gets down into the "picofaradish" range and it's reasonable to use copper pours to provide that capacitance. Most often these copper pours are in the shape of a fan (see, e.g., the photo in the first page of http://www.downeastmicrowave.com/PDF/PDF10368.pdf -- that guy makes nice stuff!), that is, a quarter-circle. Why that particular shape? My own thoughts are:

-- Well, I suppose that where you branch off of a microstrip you'd certainly want a nice gradual transition in pour width, so that leaves you with at least a "triangularish" shape
-- A "boxier" shape (either a rectangle or a triangle) probably makes a better patch antenna than something with more curved edges?
-- To cover a given area (i.e., to obtain a specified capacitance), a circle of course gives the smallest circumference, hence any resonant (antenna) modes that are created have as high of a frequency as possible (e.g., a circle is the best shape to use to make a copper pour electrically appear as "lumped" as possible at a given frequency)

Opinions?

Thanks(ish),
---Joel Kolstad

I suspect, without knowing, that the 'fan' is because the wave
propagates from the entry to the capacitor at a constant rate, so you
want to have a constant-radius end for it to reflect from -- otherwise
you won't get a clean reflection.

Someone will tell me how I'm wrong, but in the mean time I'm going to go
drip my tea off my spoon into the exact center of the cup & watch the
pretty patterns.

Scott & PD-

I agree that the transistors are most likely good.

If this microphone had a former life connected to a CB set, it may have
always had the problem. Resistors would have to drift a long way to cause
the problem, but what if one of them was the wrong value to begin with?
Perhaps off by a factor of ten?

Leakage in the 0.1 capacitor is the next likely suspect.

The diagram I downloaded doesn't have a value for one of the resistors. I
would guess its value might be between 500K and 1Meg Ohm at the input to
the first transistor.

Gary,
OK, that rings a bell. I believe a sig gen was mentioned wherevever
it was I saw the idea. The old Heathkit IG-102 is pretty darn stable,
but the resolution leaves a bit to be desired. I wouldn't be sweeping
it though, just using it as the adjustable LO. It's certainly easy
enough to try; I have a few SBL-1's and a return loss bridge.

Tnx,
Ted KX4OM

Wasn't the amplified version supposed to be low impedance?
<http://www.kb2ljj.com/data/mic/D-104.htm> shows a Silver Eagle
"Final Edition" and says "Impedance: 500 ohms max."

I do see stuff on the web that suggests that the high impedance
versions wanted no less than 1 megohm load, one saying that 10 meg
was nearly ideal.

Hello All,
I am looking for the pin out details on the eight pin
connector, a tube style connector, that is fitted to
this oven oscillator module.
DC in, Oscillator output, that sort of information.
Regards,
John

please help me with my design on metal detector.i need to mix my two sine inputs(few hundreds of KHz)and extract their difference.i opted for the bjt.my questions are:

1.biasing
-- using the buil-in transistor of lm389,how do i bias it such that it operate in "mixing" mode?

2.diode-based
-- can u share any other simple circuit to implement a mixer in the low frequency range?

thanks!!!!

There are many, many ways to implement a frequency 'mixer', and the choice of which one to select is based on even more considerations and tradeoffs, so it's a little diccicult to recommend a topology without knowing exactly what the requirements are.

However, from your short description, it sounds like you're trying to make a metal detector that works on the principle of an oscillator whose frequency changes when the search head comes into close proximity of a metal object. The way these usually work is that the search head has a rather large inductive coil that is part of an oscillator tuned circuit (usually at a few hundred KHz). The search-headd oscillator frequency is 'mixed' with a fixed oscillator a few KHz different in frequency, producing an audible beat note. When the search head comes near a metal object, the change in the oscillator frequency produces an audible change in the audio beat note.

For this type of application you can use a very simple digital 'mixer' since there is no useful information in the amplitude of either mixer input - the only thing that matters is the frequency of the beat note. Assuming that your two oscillator signals can be formed into clean square-wave logic levels, I would suggest an HCMOS exclusive-or gate for this application, followed by a simple RC lowpass filter prior to the audio ampliifier.

A little trick you might try is to connect an unused exclusive-or gate as an inverter by connecting one input to the supply. Then connect a large value (100K is fine) from the remaining input to that gate to its output. This will bias the gate into a linear mode and the output DC voltage 'idle' at approx 1/2 Vcc). If you capacitively drive this biased gate with your filtered mixer output, it will have quite a bit of audio gain. You can use the remaining gates as amplifiers in a similar fashion.

I'm sure that this thread will produce many other very good suggestions, But this one is simple and pretty idiot-proof.

Joel:

Don't think of these things as capacitors. They are really a version of an open-ended quarter-wave transmission line stub. The transmission line section (which has varying impedance along its length due to the varying width) transforms the open circuit at the big end to an effective short at the small end.

I believe (though I am not sure) that this shape produces a wider bandwidth short circuit than does a more traditional constant-width quarter wave microstrip stub with the same line width as the small end of the quarter-circle.

A search on "radial stub" is likely to turn up more info (though I haven't tried it).

Ah, thanks, I didn't realize people really were treating them as being
distributed instead of lump! (Since using copper pours as lumped capacitors
is certainly reasonable at lower frequencies.)

2092. Chokes on digital supplies

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-30 18:26:17 UTC
From: John Wilkinson <john.wilkinson@philips.com>
Message-ID: <18f0wz6jnf5c4.1g0kwod5jfsop$.dlg@40tude.net>
Source record: 12893

Hi,
If I have a few TTL chips on the same PCB as all my PLL's (see previous threads). Would it be a good idea to put a little choke in the supply line up against each TTL chip, with cap decoupling either side?

What about 100uH and 2 100nF?

Will that reduce any noise problems I have?

Thanks,
John.

2093. Re: Chokes on digital supplies

Message-ID: <e0hembeqa2@engnntp2.cig.mot.com>
Source record: 12894

I don't believe chokes should be necessary. Good 0.1 or 0.01 at each
package should be enough. Parallel bypass caps is not a good idea because
the larger one will go inductive above its self resonant freq and resonate
with the other creating a parallel resonant, high impedance "non-bypass".

HOWEVER...

Make sure your ground paths are isolated from each other. The digital chip
ground path should have nothing in common with the VCO and Phase Det
grounds. The VCO is extremely sensitive to any voltage variations between
ground and its supply and if you have ground variations and a good supply,
it is just like power supply ripple.
All the digital grounds should go directly back to the supple input to
the board and the analog grounds the same and this must be two completely
isolated paths.

Sometimes *cutting* ground paths around a VCO improves spurs.

GOOD:

```
VCO GND ----------------------\
\
-Supply GND
/
/
TTL GND ----------------------
```

BAD:

```
VCO GND --\ This run *HAS* impedance and
\ voltage drop in the form of pulses.
----------------------Supply GND
/ And there fore modulates the VCO.
/
TTL GND --
```

There are two schools of thought on RF grounding of mixed analogue and digital circuits. I have always had good results with a single, complete ground *plane* for all of the analogue and digital circuitry, and separate supplies with their own regulators near the loads (or at least their own decoupling), for the noisy blocks and the sensitive blocks. Others may say that what I do doesn't work for them, but it has worked for me.

Chris

Source record: 12798

I agree with Chris on this one. I'd add some things, though. Because of transmission-line effects, the ground return currents for digital ICs will tend to flow on the ground plane in the region very near the supply lines, so keep the supply lines for the digital section away from the sensitive analog section.

Another way to make the digital stuff quiet is to realize that a great deal of the high frequency currents involved with digital are in the I/O lines that go into, and especially go out of, chips. It helps to pay special attention to all digital signal lines. You can soften the edges by putting small series resistors physically very near each output, so as to limit the current into the capacitance of the trace and inputs it goes to. It can help a lot, too, to use differential signalling even when you don't need to. Just as differential lines in the sensitive analog input end help to reject noise, so differential lines radiate less than single ended ones. Differential outputs also make for quieter power supply lines, since one output turns on whenever another turns off, maintaining constant supply current. Fully differential ECL is particularly quiet on the power supplies, but likely not worth the effort because of how power-hungry it is and how little integration you can get on a single chip.

We do use little ferrites on power supply lines; they provide effective high frequency isolation. 0.1uF bypasses aren't really very good at bypassing 100MHz -- it's nice to also use some smaller values, and to use physically small parts that have low parasitic inductance. It pays to THINK about the layout quite a bit, and understand what you are doing and why.

For sensitive analog circuitry that draws constant current, there's a cute and very effective power supply cleaning circuit and ap note on the Wenzel Associates website. The noise out of a typical linear regulator will significantly add to the phase noise of a PLL. That site also has some good info about low phase noise circuits. (somewhat aside: Wenzel makes some really fine low-noise oscillators, and Charles Wenzel is a very nice, and very interesting, guy.)

I think this all says that what Chris does also DOES work for me, and I can affirm that much of it is in a commercial environment where we are achieving cutting-edge performance.

Cheers,
Tom

2098. Re: single-ended BJT MIXER design help!

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-31 03:12:26 UTC
From: e2 <electromagnetic377@yahoo.com>
Message-ID: <1143774746.601785.119400@j33g2000cwa.googlegroups.com>
Source record: 12799

thanks..you hit my application!
actually im targeting either diode or bjt based mixer becoz they're
available for me now.
i tried the single-ended bjt mixer..
i set the oscillators around 460khz...with a few hundred of millivolts
peak to peak..
i use the transistor from lm389n audio chip..what i did was to bias it
in its "active mode"
end then single-fed the two outputs from oscillator to the base of
bjt...
the problem is i cant discern the signal from the spectrum..but in the
oscilloscope,its
close to a cliped periodic wave with fundamentals close to the one of
my oscillator frequency...can you help me with another design
configuration with the bjt?

next i tried the diode based but i could hardly get a differnce
frequency..only harmonics though..my arrangement is each input is fed
to a 1k resistor which is then single fed to the negative side of the
diode...any help?or new configuration?

thanks!!

A balanced switching mixer using two BJTs would be a lot better. Or,
you could use bus switches as in the FST3125 which would be better
still.

Leon

2102. Re: Chokes on digital supplies

Newsgroup: rec.radio.amateur.homebrew

Source record: 12803

I borrowed 5V from the USB line of a data acquisition card -- it is somewhat noisy so I put a 100uH choke and a small tantalum on the line -- it works.

You can get excellent noise performance (far exceeding the Wetzel modified LM317 circuit) with Linear Technologies LT1763 and LT1964 ultra-low noise regulators -- they will do 100mA on their own and can be used to drive a pass transistor if you need more juice. Unfortunately, post regulating any digital supply for analog circuitry burns up watts.

fwiw -- while dual bypass caps aren't a good idea for digital circuits (because of the ringing aforementioned) -- in analog they are recommended for certain low noise apps because of susceptibility to EMI and RFI.

2103. Re: Chokes on digital supplies

Newsgroup: rec.radio.amateur.homebrew

Source record: 12804

Huh? The LT1763 claims 20uVRMS noise in a 100kHz bandwidth. That's about 63nV/rtHz. The data sheets shows it MUCH worse at low frequencies, and the LT1964 a bit worse yet. I'm not sure who Wetzel is, but the (modified) Wenzel circuit I've used has given me noise down in the very few nanovolts/rtHz region down to 10Hz and below, depending on just how I implement it. Perhaps we're thinking of different circuits for cleaning supplies. The one I'm thinking of is very useful even with "quiet" regulators like the LT parts. Easy implementations get you 20dB improvement in noise, and careful design and parts specification can get you 40dB, with noise as low as a couple nV/rtHz and a 1/f corner well below 100Hz, by using an op amp like the AD797 and low noise precision resistors in what is essentially a bridge circuit to cancel the regulator noise.

Guess the jury is still out on the multiple bypass cap values, too. Xilinx and TI at least both recommend -- strongly recommend -- multiple values. Yes, you want to avoid resonances, but I've had much less trouble with bypass caps in parallel than with chokes resonating with with bypass caps. Now that's something to look out for! The trick with parallel bypass caps is to insure that the Q of any parasitic inductances is low.

Cheers,
Tom

Tom

2106. The weeekly FAQ - What Is Ham Radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-03-31 16:06:05 UTC
From: Plod's Conscience <radio.ham@lycos.co.uk>
Message-ID: <1143821165.443067.147440@e56g2000cwe.googlegroups.com>
Source record: 12807
Cross-posted to: uk.radio.amateur,rec.radio.amateur.policy,rec.radio.amateur.homebrew

A necessary preface.....

(It is becoming increasingly difficult to fly the flag for
decency and for civilised behaviour in Radio Hammery. Even
the Usenet newsgroups dedicated to the cause have degenerated
into a hotbed of abusive onslaughts by those who ought to know
better; the Nugatory Numpties who boast of an interest
exceeding 10, 20, 30, 40 or even 50 years and yet who have
proved themselves incapable of even meeting the trivial exam
standards set for 6-year-olds. However, there still exists
the fundamental basis on which Ham Radio is based, and
that will never die. This FAQ ("What Is Ham Radio?") will
be regularly published and will not be shouted or bullied
down. It is important that those of a technical bent, who
are the natural seed-corn of Radio Hammery and who
gravitate towards us to be the real novitiate, can
still find us, (and know that we are still here), their fellows.)

-----ooooo-----

So,.....What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then

operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line

telephone, whilst continuing to regard Ham Radio as a separate technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between a Ham Radio licence and a CB Radio licence. To him, they are sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then tries to classify himself as the equal of the Radio Ham when, in fact, he is nothing of the kind.

Ham Radio is not CB Radio and has no common ground with it! Ham Radio is _THE_ technical pursuit for gentlemen; CB Radio is the operating hobby for those who buy their rigs and equipment off the shelf.

-----ooooo-----

If you are the sort of person who is motivated by a technical interest in how things work; if you took apart malfunctioning clocks, toasters and the like and put them right despite never having seen them working, then a Ham Radio licence is your traditional route! There has never been a shortage of such people, and those who gravitate towards such an interest have always been welcomed into our shacks and their interests fostered. There is not today, nor has there ever been, a need to go out and encourage and press children, children who have never expressed an interest in Ham Radio, to come into our shacks. Such an activity should cause eyebrows to be raised - what normal well-adjusted adults seek the social acquaintance of children?!

-----ooooo-----

Please remember that this FAQ is a _POSITIVE EXHORTATION_ to you to exert yourselves to join our fraternity! (If you find otherwise, then perhaps you are already classing yourself in the mediocre groups of those who are criticised in the FAQ and from whom we _MUST_ dissociate? If so - it's never too late for a re-taxonomisation on your part - there's nothing elitist about us, and we welcome all those who are prepared to put themselves out in order to join our ranks!)

By the way, did you have to install extra fans to compensate for the
low air density (and thus lower heat carrying capacity) at high
altitudes ?

Some electronic systems have quite low maximum altitude ratings due to
this. The low air density might also cause problems for amateur radio
equipment if operated at full power at high altitudes.

Your best bet would be a succession of rooftops or balconies. From what I understand, homes in Bangalore have flat roofts rather than peaked. I bet if you ask permission from half a dozen neighbors in both directions, that you can put up a dipole.

Your other possibility would be to put up a 1/4 wave vertical for 40 meters. There is some outstanding telescoping fiberglass pole on the market, just put copper tape along the side as the radiating element.

Good Luck,

The Eternal Squire

Hi Paul,

This installation was somewhere on the Andes were there was a
astronomic site.

We did not need to use extra fans or other "helping" devices. Certainly
this set-up
was not on an open air site, it was in an building. So "air" presence
was OK for humans.

BTW, in 1966 while working in UK for a small specialized company, I was
involved in a project were we were producing the Eidofor Colour TV
Projectors (Philips Group). Philips had sold 3 of these units to be
used in Mexico City for the Olympic Games. To be sure we would not have
problems with the 3 colour tubes for explosion (I forgot M.C. height
a.s.l.) we tested the system in the BAC UK air chamber (vy expensive
tubes...hi).

Hi e2,

I built a 2x bjt mixer as published by DJ2LR in the 70-80s. I had no instrumentation so I could not guess what it was wrong. It was mixing OK but it was noisy. probably not enough drive.

As suggested by Leon you could use the FST3125 and I can send you a note in english with circuit diagram and other infos on my 1 transformer double balanced mixer (demodulator-modulator) using the FST3125. A note was published in RadCom, TT column, June 04.

Pse send me an email to i7swxatyahoo.com

At sea level, the air density is about 1.2 kg/mï¿½ and at altitudes of
4000 m (La Paz?), the air density is only 0,8 kg/mï¿½. In a forced
cooled system, the critical parameter is the _mass_ flowing though the
system and the amount of degrees the air is heated.

In order to run the same mass of air through the system, you would
have to use 1.2:0.8 or 1.5 times the air volume in the mountains.

Just had a chance to disassemble it and remove the
plastic lens that creates the line-of-light, and other
optical obstructions and it produces a nice little spot
focussable with a hand magnifying glass to a very
fine spot that is uncomfortable to look at, so
presumably with a dual-lens arrangement will
give a decent parallel and non-divergent beam.

So, even if you've got no immediate use for it, a small
laser that is already mounted in a plastic housing
can't be bad for a couple of quid for future
experiments.

Anybody seen inside those devices that project
laser writing - are they just a couple of rotating mirrors
with suitable synchronising pulses being generated?

Yes, you are right -- my recollection was faulty and I apologize.

I was just looking at the "clean up" portion of the Wenzel (not Wetzel) regulator with an LM317 -- later on in the article (Finesse Voltage Regulator Noise) they use an LM833 which is cited as a limiting factor.

Jung used an AD797 in the Super-Regulator series of articles, but I believe that they switched to an AD817 or AD825 later on as there were some problems. The Jung article can be found on EDN's website: www.ednmag.com -- Just put "Jung" in the search engine. Some people reported that the Jung super-regulator could be made to oscillate pretty easily. I didn't have this problem.

I built the super-regulator and used it with a low noise preamp, but found the Linear Parts to be much easier to implement, as long as I used a tantalum bypass !

You've got that right!

I'd be very careful sticking a choke, especially one without a swamping resistance in parallel, in series with a supply line! Unless you hve a specific frequency range you have to block an L/C filter can be big problems.

Loads of BS snipped....

I see you are also short on responses to this list of questions that
were asked of you earlier today. Care to answer them or are you going
to be a hypocrite all your life?

Plods Reunited wrote:

And your answers are? Simple "yes" or "no" answers (sound familiar?)
will be fine, except for the last one where a simple figure will
suffice. Or are you going to run away with your tail between you legs
like you accuse Brian of doing?

Hi Paul,

I do not know but in middle of 60s that was the only TV color
projectors
designed by a Swiss engineer, assembled by Peto Scott Instrument Ltd
for Philips
in Addlestone, Surrey UK.
It was tested in the central lab were we were mainly working on
military equipments.
Many of those big blocks were sold world wide. I do remember the Mexico
Olympics
because we had to do that special test in the chamber room were
airplanes were
tested for all 3 machines.

For Peru', I believe it was somewhere over 2000 meters asl and it was
not later than 1980.

Ted, Dale, Ken,

Ken that is true about the hen's teeth. I think that price is worth it though. Dales receiver looks like a 2B. The blue backlighting is really cool.
I just like making homebrew verniers and dials but am getting lazy and have been using Jackson Bros.stuff for the last two projects. I tried what I believe is an Oren Elliot drive but it is so stiff I didn't use it. One of the last projects used a small CD for the dial. Looks clever and homebrewish but kinda tacky too. I am dangerous with certain tools in my hands so I try to use ready made stuff. But the dial on my SSB transceiver needed a little more work due to the way the dial had to mounted. I am pleased with my mechanically challenged self. I'll follow Dales and your advice and create it on my PC. Sharpy usually used here.

Ted, on the VFO I roughly calculate the L and C from a few old DeMaw and Hayward publications. But I generally go for less L more C. I think those calculations are rough approximations anyways. I think the 2nd edition of DeMaws QRP Notebook has the rough equations for Colpitts and Clapp. I haven't seen one for Hartley. I have several old toroids wound that I use for various things like VFO's. I used a number in the Huffpuff circuit Hans Summers designed and substituted for experimentation and optimum performance. I also have a bunch of cut and try capacitors I use when I am building something like a VFO. I am afraid to admit I do a lot of empirical construction on VFO's. Just the opposite on filters and amplifiers. I use my SA when I build LC filters and I measure all my critical L and C with my homebrew LC meter.
One thing I learned was to use ugly construction on my VFO's. I don't know the fellow but W7EL mentioned something somewhere that made me try that method. It simpler at the very least.

Ted maybe I'll catch you on the other site but did you get the VFO working? I knew you were working on a Hartley Huff Puff VFO. I tried link coupling on the output from my Pierce version from the coil and was suprised at how much cleaner the output was. I was going to try the control circuit from a link too but had my grandson over the last two weekends. He is just discovering his feet and rolling over. It is an important time for grandpas.

Its spring yardwork weekend here so not much radio going on. BTW, what is a Nugatory Numptie (see other post)? I could be one. Do we have a website?

Dale's receiver looks like it belongs in a hospital, inside the case, anyway...I'm sure an artificial liver or whatever doesn't have any more "tubing" connections! That's taking the art of modular construction to a whole 'nother level! The receiver also looks very "sanitary", as we used to say back in the '70s, or I guess the word would be "sick" in today's vernacular. More hospital tie-ins, yuk-yuk!

I won a door prize at the last NoGa meeting of a National Velvet vernier. I don't have it handy for the number, but it's a fairly small one...the dial area is about 3" wide. The cardboard scale has been humidified somewhere along the way, so I'll need to scan that and redo it in photoshop. The gears are ok, but a bit stiff. It looks like it will be perfect for a VFO, maybe my long-wanted heterodyne VFO for the HT-40.

From what I understand, all other things being equal, the inductor is more likely to suffer the effects of temperature-induced drift than the capacitors, as long as C0G/NP0 and polystyrene caps are used. Therefore, it makes sense to have a higher C to L ratio, although the configuration of the VFO circuit will probably impose limits, as in failure to oscillate at some point. I generally look at somebody else's design as a prototype, and try to work around the same ratiios.

I went over and over the calculations again, and I'm pretty sure I'm right, and there's a typo in the "Progressive Receiver" appendix. Then it suddenly occurred to me, " Why don't you just lash up the capacitors and the inductor and measure the darn thing?" Duh! I have a grid dip meter, and I'm still making use of my cheap-but-fairly accurate Rainbow capacitance meter, the one from the Handbook, until I get the PIC programmed for the "Everyday Practical Electronics" one that the Columbus QRP club built. This mystery will soon be solved!

One of the Hartley designs I'm looking at for the LO of my EMRFD transceiver project is the Fig. 6.148 4 MHz one, which I would conver to 5 MHz. Now that one is tapped, but what you did Don was to not tap the coil, but to add a coupling winding, as I understand it. In the Figure I just mentioned, Wes has an MV209 on the tap for fine tuning, so I guess that's where the Huff and Puff would attach.

The other circuit I've been studying to the point of actually cadding it, is Figure 12.25 in EMRFD. That one also has the familiar C1 C2 C3 Cvariable issue I've been trying to figure out, as does the Hartley above. This VFO is a Colpitts, though (I guess; the output is off the gate alone, and not the source). I suppose I'd either tap onto the coil or use a coupling winding on that one, similar to what you did. Conveniently, this one is a 5 MHz VFO already.

I just put in the order to Digi-Key a couple of days ago for the chips for the fast stabilizer, so no, I haven't built it yet. I decided not to go ahead with the other 2-chip minimalist one after your suggestion on the fast one. The crystal oscillator I ordered is 66.66 MHz, so it should work.

Source record: 12832

Using those old verniers is risky to me only because finding replacements if they start to slip or have backlash. I at least try to find or build something I can replace. But the Eddiestone are just so nice looking.

What I did on the HP VFO was like in fig 7.27 EMRFD. The output of the IC is a square wave. I was concerned after I looked at the output on my analyzer. I see why the cmos marker generators are so popular. Strong harmonics way above 100MHz. The output was significantly cleaner from the tap. Right around then I decided to go back and finish my SSB receiver and mount it in the chassis so I didn't have to use so many clip leads while I was playing with it.

I was going to do something similar to the fig 12.25 mixing type LO and I still may. My original receiver had a 9MHz filter but a relatively strong birdy from the LO at 7.2MHz. I decided to just change the filter to 9.216MHz and no birdies. Was hell trying to find closely matched 9.216MHz crystals though. I got 65 ea from Mouser and only got ten within 5%. Mostly a wide discrepancy in ESR. I guess you can make up for a lossy filter but after spending as much time as I did on both filters in measuring crystals I wanted something to show for it.

I was going to try the control circuit on the tap in my HP VFO. I know it will work thiough even though I haven't tried it. Its just getting the correct link and varactor. The fast HP VFO's still amazes me. I get started on too many things so I went back to my SSB rig.

On the inductor drift I agree. I seem to have luck with slightly lower L and using the slight neg temp coefficient of the COG caps. I did that in my tube receiver built with toroids. I ended up using a small silver mica for temp compensation of all things. Like you I look at other circuits and copy. I didn't on this VFO because I was copying my own circuit that worked before from something I am sure I copied. The more I try other things though the less I copy. Right now I am working on a 25 VDC 6AMP power supply for the transceiver. I am going to try power mosfets again as I had good luck in the last low power linear I built. I am only looking for 40W or so. Plenty big for the type of SSB I will work. I have a 28 VDC 3 A supply I made years ago. Just not sure it is big enough for the PA I am going to use. Its not that efficient.

Gosh, typo errors in ham publications! Hard to believe! Not!. Good for you for checking. I have a mess of spreadsheets with most of the common formulas. I also made some for double and triple tuned BP filters, feedback amps, my LC meter calculations, a logarithmic power meter and crystal parameter testing. I check a lot of circuits in books by plugging in the data to my sheets.

EMRFD is a great book. One thing I have been using in my transceiver LO now is the hybrid splitter shown in fig 6.75. The vfo in 12.25 shows a resistive version. I used the hybrid on both my VFO and BFO. That is a nice technique even if it is a few more parts. I guess Wes must be a better Numptie than all of us?

I bet you will really enjoy experimenting with the fast HP VFO. I haven't had that much fun with a simple project in a long time. Once you build a few you start getting alot of ideas on how to use it. Then it starts adding to your list of projects. You start losing sleep, the wife keeps asking you to take the trash out, you stop shaving, grow your hair long and start smoking and drinking too much coffee. Then you are in Nugatory. Thats ham purgatory. My wife calls it the doghouse.

Maybe I will put a picture of my progress on the SSB transceiver on the tech site soon. I never know what Chuck is willing to accept though. So I get a little cautious.

Keep me up on your progress.

Source record: 12833

Hi Don and Ted,
While it has been over a year now since I did the VFO- I too had some difficulties with the QST values. In talking w/ W7ZOI, Wes indicated that some errors had worked their way into the design over the years. One was on the audio amp- values I had caused severe rolloff below about 2KHz- making SSB very tinny.
The other was on the VFO. Because of the Eddystone dial, I wished to make the VFO as linear as possible- book values led to a highly non linear scale. I do not recall exactly what I did- although I played with the math for a long time- to lienarize it- but I would trust your calcs.
At some point I will open her up again as I want to buffer the VFO and tap off for a TX VFO- the plan is to build a Drake style reciter for the RX- and at that time will better document the changes I made.

2133. New program. Coils and Transmission Lines.

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-02 04:16:50 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <WeqdnQW1cffCzbLZnZ2dnUVZ8tydnZ2d@bt.com>
Source record: 12834

NOW AVAILABLE ** New Program "TRANCO_1.exe"

This program analyses performance as a transmission line, of a
single-layer solenoid coil which may be inserted in an antenna wire.
The coil itself may be used as a very short vertical antenna at its
1/4-wave resonant frequency.

From the input data of length, diameter and number of turns, the
program calculates inductance, capacitance and resistance of the
equivalent transmission line. The secondary constants of
characteristic impedance Zo, phase shift, velocity factor, and
attenuation are calculated. Also the feedpoint input impedance, R+jX,
for when a coil is used as an antenna.

Because of the sensitivity to the environment of such an antenna and
its high Q it will be necessary to trim antenna length to a particular
wanted resonant frequency.

Download TRANCO_1 in a few seconds from website below and run
immediately. Filesize = 38 Kbytes. (It's at the bottom of the list.)

....

Source record: 12835

Hi Steve,
If you are interested I had really good results recently with a homebrew RLB, in fact so good that I doubted the results and had to redo them several times before I was comfortable I hadn't made a mistake, and I probably still have but anyway it works heaps good enough for me. Basically using the non lab standard test equipment I had available it shows a directivity of better than 40db from about 1 to 500MHz. I found the best results by using a more or less current balun with coax, and a balancing extra bit of coax, and paying close attention to keeping everything balanced/symmetrical and having the reference connected with a connector identical to the unknown, rather than just a 50ohm resistor directly connected. See writeup in December issue of Nerg News
http://www.nerg.asn.au/NERGNEWS/NN200512.pdf

Does anyone have a link to a website for making a high power Z match? I have made the 100 watt version with the toroid core and broadcast caps which really works great. I thought maybe there might be a design out there using heavier toroids for more wattage (500-1000 watts). Thanks for any info, Rob

No - it's because we see the word "FAQ", see who's posted it, and we
all know it's going to be the same deranged drivel that you post every
week.

Now faq off and play on the M4.

Yes - and also that innocence can be proven by standing in the police
cell all night with a blanket on your head singing
"I'll sing you a song of social justice,
"BROAD-HURST!! BLAKE-LOCK!!,
"Of two deserving deaths, of public justice.
"BROAD-HURST!! BLAKE-LOCK!!"

Brian,
What I read of it looked good. On your section on GPS time, you might
note that GPS time does not include the leap-seconds that clock time
does. I believe that there are now 14 leap seconds difference between
GPS time and clock time, but that should be verified (it might be 16).
The handheld GPS receivers I have seen, correct for the difference
before displaying the time. Industrial units may provide either at your
option. I believe that you can get 50 nS accuracy out of the industrial
units (specifically the old Motorola Oncore series).

Dale & Don,
I haven't had a chance to lash up the components yet, but I checked my spreadsheet using Wes's example on page 4.4. The numbers check out; unfortunately, Wes specifies a value for C3 in the EMRFD example, and in the Progressive Receiver Article, C3 is the unknown; i.e., how much additional capacitance you'd have to add in parallel with the coil to use a specific variable cap in the given configuration.
Now that I can see the "C12v" equation in EMRFD, which is not in the QST article, but I've modified my spreadsheet to include it I can check the resonance using the given values for L.

Dale, when I looked at your jpg's again yesterday, I noticed that you've modified the receiver internals a lot since I first saw the rig. Since the links I had were to a directory on your commercial site, I'm not sure if you have another site where you described what you did.

Early last Spring, I got rid of all my new-fangled ham rigs, like the FT-817 and the not-so-new, but pristine TS-530s and bought an HW-101 and some equipment to restore. Homebrewing and boatanchors is what I'm about now. I did the VFO alignment on the HW-101 and was able to get it within 1kHz, end to end, as indicated on the dial, anyway. That surprised the heck out of me. I've since acquired an LMO from an SB-401 that I'm going to put in a project somewhere along the line. I have a complete set of Heath HFO crystals, and both CW and SSB filters from another source. I might make myself a broadbanded QRP rig out of those.

I'm using that design because I'll need 2 HFO's in two separate rigs
I'm working on. That one is interesting because of the 5 MHz output,
but I won't be using that for the rig itself. I'm using a 74HC4053
switch to mix either of two LOs with the 5 MHz VFO. The transceiver
I'm using EMRFD circuits for is a 15 and 20 meter SSB/CW traansceiver.
I'm using a 9MHz If, with HFO frequencies of 25 and 18 MHz. I'll use
the sums to produce the correct LO frequencies.

The other rig is one I've been working on, off and on, for over a
year. That one is based on G4GXOs Belthorn SSB/IF module. I picked
an IF of 11 MHz for it, because 32 and 25 MHz HFO crystals will allow
me to use a VFO of the toal span of 3.890 4.148 MHz. All of the
crystals are Mouser 39-cent variety.

I didn't realize it, but when I put in my order from Digi-Key last
wee, I stumbled across the ECS 18 MHz crystal, a value I didn't have
in my data base of available frequencies...that allows me to make the
EMRFD rig a 2-bander, adding 20 meters!

>better Numptie than all of us?
I'm not sure I really knew much of anything until I got EMRFD. The
first few weeks, I had a running stream of Q&A emails with Wes, and he
was kind enough to be patient and explain some things. One in
particular was a problem I had in adapting a published L-network to
the actual impedances of my crystal filter in the 30 meter rig I built
for Straight Key Night .

In Fig. 12.25, he's actually using the take-off point from the VFO to
the mixer from the attenuator pad for the 5 MHz output, to get the -10
dBm for 5 MHz for the 20 meter part of the rig.

Sleep? What's that? Fortunately, my wife is busy getting her business
up and running, and I have plenty of time on my hands (I've inherited
the dog and cat-tending responsibilities).

>Maybe I will put a picture of my progress on the SSB transceiver on the
>tech site soon. I never know what Chuck is willing to accept though. So
>I get a little cautious.
I understand completely. However, why not start a folder anyway?
There's only a couple of them there, and it's not like it's stuff that
belongs in the Smithsonian. Now if Dale had his receiver on the site,
that's certainly Smithsonian-quality!

When I was building the SKN Special, I did running updates to the NoGa
list with the latest photos on my web site. Now that it's finished, I
recently went back and reorganized that page to reflect past tense.
One of the highlights was definitely getting the VFO going. On the
scope, the signal has a weird distortion in the sine wave, like the
trailing edge is partially scooped out; I should post that on the
yahoo group site and see if anyone can figure out what it means. But,
since it's feeding an NE602, and they can take square waves, I guess a
little distortion doesn't matter.

>Keep me up on your progress.
Tomorrow, I lash up a test capacitance circuit. Then, once I can
finally do the math and figure out which variable I can use, I'll
start building. the Digi-Key prts for the Huff and Puff whould be
here mid-week.

72/73,
Ted KX4OM

Hi Ted,
I quickly looked at the VFO schematic in my1994 Handbook that had the PR. I
seem to recall in the end I replaced C1 with a short- just eliminating it.
Not 100% positive, but think that was what it came down to in order to get
good linearity out of my VFO.

Dale

2151. QRP 5W HF linear amp transistors and design

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-03 13:12:59 UTC
From: Richard Hosking <richardh@iinet.net.au>
Message-ID: <44311f5c$0$2111$5a62ac22@per-qv1-newsreader-01.iinet.net.au>
Source record: 12752

Dear all
I want to build a power amp for SSB HF 1.5-30 MHz
Specs
approx 5W out
Cheap/easy to source components
Surface Mount parts/small
Rugged/stable into any/most loads
Gain around 40 dB
Flat gain to 1 dB or so

Thought I would do something like

Class A MMBT2222 -> 2X push pull MMBT2222 -> finals push pull balanced

What to do for the finals?
I looked at the PD55003 RF MOSFETS - can you get these easily?
Will they work down to HF?

What other issues?
What about transformers?
Is this a practical proposition?
I havent seen any similar designs

I would be grateful for some pointers

Thanks
Richard

Paul:

Thanks for the info....that's an interesting balun approach. I was thinking about the two-connector approach and using a good microwave load for the termination, but decided it wasn't likely needed for 50 MHz and below. Though with the results you are getting it's tempting to build another one for VHF/UHF. But I need a good signal generator first !

I have since obtained much better results than I was initially getting, with two main approaches to improvement:
(1) I changed the balun to 12 bifilar turns on an FT37-43 core, which now has enough inductance for reasonable measurement accuracy at the lower frequencies (though the degradation is still pretty noticeable with good loads that read >35 dB return loss at 10-30 MHz showing as 25 dB at 1.8 MHz). A few more turns would probably be better.
(2) I spent lots of time chasing down leakage paths and sensitivity to leakage...grounding cables, reducing attenuator on signal generator, scraping paint from inside front panel of signal generator, removing microphone from transceiver in use as a detector, etc.

I don't really understand the leakage paths, but I was able to get their impact down to a much more usable level. Clearly a high standard of shielding on all components of the test setup is a must. I'm now getting around 0.5 dB change from open to short at 30-50 MHz (insignificant at lower frequencies) and my good loads read 31-34 dB return loss at 50 MHz, which is probably about what should be expected due to the adapters to PL-259 plug. I am not yet quite fully confident when measuring antennas though, due to somewhat greater leakage effects into the receiver.

> What to do for the finals?

Generically you are in the "CB final" transistor class.

They don't sell as many CB's as they used to :-).

Good starting point is RF Parts' webpage:

http://www.rfparts.com/transistorspecs.html

> I havent seen any similar designs

Communication Concepts has many Motorola app notes online from the 70's
that cover this with bipolars. e.g. AN779 with MRF475/476. A lot of
these app notes ended up being repeated almost verbatim as QST
construction articles. In some cases they sell PCB's and component
kits:

http://www.communication-concepts.com/

Ummmm, no.

> Towit you have the eastern time zone 7 hours ahead of Zulu time. My
> gawd man can I get the same time machine you have?

The version of the page dated 2006 April 2 has the following:

PST PDT MST MDT CST CDT EST EDT UTC
4 p.m. 5 p.m. 5 p.m. 6 p.m. 6 p.m. 7 p.m. 7 p.m. 8 p.m. 00:00

Which is correct, showing the EST as being 5 hours BEHIND UTC (or 19
hours ahead if you think mod24)

> Lastly your conversion table doesn't have all Canadian time zones eh?
> Guess Newfoundland doesn't exist in your reality eh?
>

That is true -- nor does it include time zones for Alaska, Hawaii and
the Aleutians.

It is hard to beat CB PA and driver transistors for this job.
2SC2166 makes a great driver. If you only need 5W, you could
use them as the final stage. For slightly higher power levels,
the 2SC1969 or 2SC2312 are a good choice. The 2SC1945 is particularly
attractive because the HS tab is connected to the emitter rather
than the collector. Genuine Mitsubishi are usually better than
unbranded generic transistors. http://www.grandata.co.uk usually
have the best prices for Japanese transistors.

My experience with modern devices is that you can easily
get them for free as samples but you can't buy them for
love nor money :-)

The Philips BFGxxx series of surface-mount transistors are readily
available on this side of the planet.
BFG235 12V 2W and BFG135A 15V 1W have multi-GHz ft and
are available from Maplin.

Any of the crystal manufacturers should be able to supply these. It
might be expensive, as they generally have a minimum order amount.
Golledge, for instance, has them as a standard part. I just wanted one
25.175 MHz oscillator once and they sent me a few as free samples. 8-)

> for any info, Rob

Assuming a constant Q or quality factor, the power handling of a toroid is proportional to its surface area. Thus, to handle 10x more power, you need 10x more surface area. A double thickness T400 toroid, 4 inches thick and 1.3 inches in diameter, should handle 600 watts, assuming the T157 worked well at 100 watts. A stack of two T520 toroids should handle a kilowatt. In practice, the optimum Q moves lower in frequency as the toroids get larger, which isn't necessarily a problem, since hams tend to need more power on the lower HF bands.

Dale,
I'll check that out. My value for C3 from the spreadsheet came out to
be 319.1 vs the 127.02 in the magazine. I used the spreadsheet on the
example on page 4.4 of EMRFd and it worked out ok. In the QST
example, setting C1 to a very low value actually increases the
discrepancy with C3, though. More mystery!

2173. Question about auto antenna cable and connectors

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-04 19:17:12 UTC
From: Ronnie <rhughes4-removeme@swbell.net>
Message-ID: <YCzYf.64385$Jd.48901@newssvr25.news.prodigy.net>
Source record: 12774
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Hi,

This is not about ham radio, but rather a general question
about the type of cable and connectors that were found
between the antenna and the AM radio in GM cars in the
60's. I'm trying to locate some technical information about
the cable and a source for the cable and connectors.

I have an old airplane autopilot system that uses tuned circuit
to sense changes in the airplane's attitude and the position of
the control servos. Distributed variable inductances and
variable capacitors combine to establish the resonant
operating frequency of the system. The components are
connected together with specific lengths of cable and the
service manual points out that the lengths are critical because
of the added capacitance of the cable and connectors.

The cable is marked as follows:

"I. T. & T. Federal Cable R.E.C."

It is a shielded cable with a spiral wound center conductor
that looks very much like the antenna cable I remember finding
in GM cars in the 60's. It also has the same type of connectors.
There is a center pin for the center conductor and a metal sleve
that extents back over the cable and makes a connection with the
shield and chassis of the radio. Friction holds the connector in
its mating socket - there are no threads, just a couple of splayed out
areas on the sleve.

I was hoping one of you might be able to point me to a source
of technical information about this cable, such as the capacitance
per unit length, etc. The one piece I have measures about 10.5 pF / foot
or 415 pF / meter, but my measurements may not be all that accurate.

Also, a source where the cable and connectors can be found today
would be appreciated.

Thanks in advance for any help.

Ronnie, N5CSE

Re: Want a Maxom Antenna Matcher

I'm looking for one of the Maxcom Antenna Matcher Units. If you have one you'd like to part with for a fair price... please email me at the below email address, or take out the NOSPAMPLEASE from the reply header above.

I know some of you are laughing because of what the Maxcom really is inside, but I'd like to buy a used one anyway.

Thanks for reading this post

cheers,

skipp

The coax used for every car radio of that vintage I ever saw (and I saw a lot) doesn't fit your description. It had a single, small diameter (#28 or so) wire rattling around loosely in a thin polyethylene tube, which was covered by a braided shield. The objective was to minimize the capacitance, but there obviously wasn't any control over Z0 or delay, since the small wire was free to move around inside the much larger diameter PE tube. There was no helically wound conductor. I think you might be looking in the wrong place for what you need. The connector fits your description, though.

It was RG62 93 ohm coax. The connectors were called "Motorola"
plugs.

Certainly not in older radios. I don't know what they sell nowadays.

I've seen that 'spiral' type of cable. They basically used the spiral as a means of maintaining the centre conductor in the average 'middle' of the hollow dielectric.

The combined inductance and capacitance of the old cable was somewhat critical but the older radios provided an antenna trimmer to compensate for the variations. The electrical model was essentially a "voltage probe" and doesn't necessarily follow common antenna/feedline rules and thought.

Thanks Bill.

The autopilot service manual I have shows a hand
drawn figure of the cable that indicates a curly or spiral twist
to the center conductor which appears as you stated to help
keep the center conductor in the middle of the tube. It also
mentions that the characteristics and length of the cable is part
of the tuned circuit, but doesn't give any data on the cable.

Like you, I'm sure I've seen that type of cable somewhere in
the past and thought it was in an automotive antenna application,
but it could have been elsewhere.

Thanks Roy. Now that you mention it, I do remember
the straight center conductor inside the much larger diameter
PE tube. The autopilot service manual I have shows a hand
drawn figure of the cable that indicates a curly or spiral twist
to the center conductor which appears to help keep the center
conductor in the middle of the tube. I also mentions that the
characteristics and length of the cable is part of the tuned circuit,
but doesn't give any data on the cable.

The connectors are like the connectors that were on the auto
radios back then. I wonder where those could be found today.
I can't seem to find them in any of the distributor catalogs I have.
Maybe a trip to an automobile junk yard.

Just wanted to share this link for anyone that is thinking of making your own pcb's.
This link is to the web site of tom gootee. It is a very well detailed step through on making pcb's using the toner transfer method, but not with the expensive toner transfer paper. I have tested this (Jet PRINTPHOTO - Multi-project photo paper) with much better results then I got with the high priced ttp.
http://www.fullnet.com/u/tomg/gooteepc.htm
Take a look, I was very impressed with the results.. JTT..kf4huf

2183. filtering of LO signals

Source record: 12784

Hi,
In my dual conversion receiver, I have a 45.455MHz second LO and a 45 - 75MHz first LO.
First IF 45MHz second IF 455KHz
Both these feed double balanced diode 7dBm mixers.
Also I have not filtered these signals at all, and the first harmonic is roughly -20dBc - -30dBc.

Is it imperitive that I filter these for my receiver to work?
If so by how much?

Best regards,
John.

Source record: 12787

Hi John,

If by 'first harmonic' you actually mean the second harmonic of your LO
(the 'first harmonic' usually refers to the fundamental frequency), the
answer depends a lot on how well your input is filtered, and on what
you have after the mixers.

This sounds like a 0-30Mhz shortwave receiver. If your input does not
have a good low pass filter for example, you may find strong FM signals
getting into the first IF passband as a result of the 2nd LO harmonic.
Note that your mixer inherently responds at odd harmonics of the LO
(3rd,5th...) and filtering odd harmonics out at the LO port does
little, so a good low pass filter is necessary anyway.
The second mixer is probably not as critical. Others will probably add
some more information.

Regards,
Glenn AC7ZN

2187. New program. Input Z of loaded line

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-05 13:25:22 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <FYednd CEmOzjWK7ZnZ2dnUVZ8smdnZ2d@bt.com>
Source record: 12788

NOW AVAILABLE ** New Program "INPUT_Z.exe"

This program calculates the often required input impedance, Z = R+jX,
of a coaxial transmission line when terminated with a load impedance
such as a radio antenna. It uses full classical transmission line
formulae and therefore avoids the errors inherent in the Smith Chart
at the lower radio frequencies.

Also calculated are line attenuation, reflection coefficient, angle of
reflection coefficient, SWR, power efficiency, and the line loss in
decibels in the presence of SWR.

Input data of frequency, line length, load resistance and load
reactance can be varied in small increments from the keyboard to allow
line behaviour to be observed. The diameter of the coaxial inner
conductor is also input, this being needed for calculating loss in the
line which affects input impedance.

Download program INPUT_Z (40 K-bytes) in a few seconds from website
below and run imediately.

Hi all,

Just bought this power supply and it turns out to be 24V as opposed to 12 as I'd hoped. It's a heafty beast and should be good for running my HF mobile if I can drop the voltage down to 13.8 whilst retaining about 20 amps for the rig's TX current draw. I know I can buy a commercial dropper, but that'd be cheating, so can anyone suggest how I might acheive such a device through HB-ing? Which active devices would be best for this purpose? I'd like over-voltage protection built-into any design put forward if possible. Any pointers, please.

Thanks!

What you're saying is: You want to build a 20A 13.8V power supply with
OVP. That it happens to take 24Vdc instead of 120Vac is trivial.

Your options are -- design a nice switching converter (which based on
the tenor of your question is beyond your mettle at the moment) or
build an enormous linear regulator and dissipate a couple hundred
watts making a very nice place for the cat to nap :) Best to set that
24V supply on the shelf, hope some day to find a good use for it, and
either buy or build a 13.8V supply from scratch.

Light aircraft switched over to 24 volt electrical systems sometime in the mid 1970s. You can sell that thing for a pretty penny to an avionics repair shop and get what you wanted in the first place.

If there is a small civilian airport near you, inquire about where they get their radios fixed and take a trip to the one that seems most viable.

2196. making a uhf bandpass filter using semi rigid or hardline?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-05 17:47:58 UTC
From: "tucker@conninc.com" <tucker@conninc.com>

Im trying to build a preamp for the 902-928 band, I bought several
surplus cellular preamps
in a auction, these had 824-855mhz ceramic filters. I took the filter
out and the noise floor
took off, i need to replace the bandpass with one in the 902-928 mhz
range. I have some
semi rigid coax .080 and of various sizes of small hardline .250 -
.540. In the past ive seem articles on making preamps & filters using
semi rigid coax but cant find any now that im ready to start building a
ATV receiver.

We purchased a new 5th wheel trailer a month ago and had to replace the stereo unit. Was I surprised when I pull the old one. It used the old Motorola auto antenna connector and cable to the antenna on the RV roof. So, I guess the antennas, cable and connectors are still being made and used today.

OR...OR...how about ... Unwind about half of the transformer secondary
and fiddle with the regulator (appropriately). You should maintain the
current level it originally had. The potential (sorry for the pun) for a
fault causing a disastrous overvoltage is less as well.
However be aware of the overhead voltage-- that is the difference in filter
output voltage relative to 13.8, so you have enough room for the regulators,
the ripple and mains dips. I did something like this with a 24V 5A supply
long ago to get 5V 25A (5V. TTL logic was big then). I actually rewound the
secondary with bigger wire to get the higher current capacity. (also a
slight tweek on the regulator topology for improved overhead). It had the
common 723 regulator topology, so changing voltage was simply changing a
zener and I must have beefed up the series pass transistors.
Of course not knowing what your regulator topology is, this could be hard.
I also have a 15 amp., Kepco, rack-mount linear hernia generator. Then,
recently, a $99 MFJ 25 amp, hold-it-in-one-hand switcher. The ham fund had
it and it took a lot less time than the re-wind.

Nope. That's where. Autos. A piece of spiral plastic "rod" around the
solid wire center conductor to space it in the center of the over-sized-hole
dielectric. I thought it was also a "Motorola" connector, but didn't want
to sound arrogant (still working at the circle M Ranch, you know). The AM
receiver antenna was (is) nothing more that a capacitive probe hooked to the
input, so the smaller the loading cap the better.
Gee, if I shill have some around, perhaps some experimentation to determine
the Z0 ... OK ... project 9,735, on the list for retirement. (yea, right)

73, Steve, K9DCI

I only saw it referred to as low capacitance cable. Don't know if the Z0
was specified

One of the engineers at Delco told me it was RG-62, and 93 ohms when
I was going to their annual car radio training back in the early '70s.
IBM also used RG-62 on their coaxial computer networking, but they used
BNC connectors.

The automotive coax I'm familiar with isn't RG-62.

Like automotive coax, RG-62 has a thin walled hollow insulating tube. But RG-62 has a polyethylene "string" which is helically wound around the center conductor to keep it centered in the hollow tube. The coax in every old automotive installation I've seen lacks this PE "string", so the center conductor is free to flop around inside the hollow tube. The effect of the "string" is to make RG-62's Z0 constant and predictable, and it will also increase the capacitance somewhat. Constant Z0 isn't important for the automotive application, and low capacitance is important.

It seems to me the center conductor is smaller in the automotive coax than in RG-62, also.

Roy is right. I looked up RG62 and this is not the cable I have.
Here's what the autopilot service manual has to say about this
cable.

"The coaxial harness assembly CD-1, 2 and 3 is manufacued to specific
lenghts and since the cable is a part of the tuned circuit, these lengths
must
not be altered. The sensor leads are made of very fine wires that are fed
through a hollow insulator. Note that the fine wire has been coiled to
provide flexibility and reduce the possibility of beaking and causing an
open in the circuit."

The diagram shows a hollow tube with a fine wire that is coiled running
through it, a braid style shield over the hollow tube and an outer jacket
over the braid. It seems to be a variant of the auto coax where the fine
wire center conductor has been coiled instead of being left straight.

Thanks for all the help with this, but don't worry yourselves about it.
I have all the orginal pieces with connectors intact, but I was hoping
to find the technical specs on the cable so I could understand the
cable's impact on the resonant frequency.

==========
Perhaps the transformer secondary winding has some lower voltage taps
which would enable you to use for 13.8 V operation ,having to waste less
energy and coping with the heat sinks and pass transistors fitted.

Another possibility is to connect the PSU transformer's primary 230/240
winding to a step down transformer's 115 V or similar lower voltage
winding ,provided the step down transformer has the same or higher power
rating than the one of the PSU
In principle the stepdown transformer could be an auto-transformer
(including a variac set in fixed position) ,obviously of adequate power
rating.
Some variacs (like the 8 Amperes unit I have) also have a fixed centre
tap , meaning that with 230V input they give a variable output as well
as a fixed 115 V output.

A stepdown transformer could also be a high voltage transformer say 230
to 500 V or similar but reverse connected (again : of adequate power
rating).

In all cases you would have to change the voltage control circuit ,such
that the voltage can be set to 13.8 V . The latter 'might' only involve
changing some resistors and/or a zener diode .

From: KC2PIH@gmail.com
Message-ID: <1144285527.509158.72800@e56g2000cwe.googlegroups.com>
Source record: 12706

Hello - I've got my hands on an HF amp and I just don't know about the quality of the low-pass filter in it. It appears to have a 5-element Chebyshev low pass filter in it. I don't have anyway to measure the values of the inductors or capacitors used in that circuit. When I drive it above 25Mhz (into a dummy load of course), the SWR is low. It has four MRF-454 transitors in it and when I drive it with 25-30 watts, I see 400+ watts out PEP. The SSB audio sounds clear too, so without understanding the circuitry fully, it seems to be biased "above" class C.

However, when I drove it on 14Mhz, the SWR was good when I drove it with 10 watts or below, but when the drive power goes up, so does the SWR.

Any ideas on what is causing that?

Thanks!

Scott McClements

FLEA all SUMMER at MIT
Sunday April 16th 2006
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

I saw both types on car radio antennas, and some was clearly marked
RG-62. Both types meet the original RG62 specification, they just use
two different methods to minimize dielectric losses, like fused disk
hardline used in CATV and other applications that require low loss
cabling. Also, why would one of the Delco engineers who designed their
car radios lie about the coax they used? He was explaining the then
brand new AM/FM/8-track combo when I asked a number of questions about
the RF front end. As usual, you will continue to believe whatever you
want to.

I happened to find a piece of the automotive cable -- complete with connector -- in my junk box, which I'm pretty sure was cut from a replacement antenna probably purchased in the '70s. This particular cable lacks the PE "string", but the ~#31 center conductor is crimped in a sort of zig-zag shape to keep it in place in the hollow tube. The aviation cable apparently has the center conductor bent into a (presumably loose) helix for the same purpose. I've never seen RG-62 cable without the PE "string", but don't have any trouble believing that someone might manufacture it without the "string". I also don't have trouble believing that some auto manufacturers might use RG-62. Although I saw a lot of auto installations in the '60s, when I moonlighted repairing such things, I never saw RG-62. But I certainly didn't see anywhere near every possibility, and I could have missed seeing a marking.

If the amplifier is distorting, you may be getting 2nd or 3rd harmonics of the 14MHz. Perhaps the output impedance of the amplifier is not 50 ohms at the harmonic frequencies and so you will see increased VSWR. I don't know what the topology of your amplifier is but if it's push-pull like many solid-state amps, then it's probable that the harmonics are third order.

Assuming your SWR instrument is reliable at 10 W (which you should
test with a reliable, say 100 ohm dummy load), an other suggestion is
that there are some flashovers in some reactive components. Is any
capacitor or inductor getting hot after a long test ?

noticed that my reception in the higher (170mhz and above) was
distorted. i also noticed a marked reduction in transmitting power in
the high frequencies, stations i could reach at 140.20 couldn't be
reached at 172.15, they couldn't reach me either at 172.15 though we
easily could reach each other at 140.20

the low (140-148mhz) seemed to work ok.

i am studying the electrical diagram if i also have to remove the other

diode to improve higher VHF freek reception.

what you guys find out so far?

Steve,
Yes the connectors can make all the difference, as you would have seen from the write-up I used BNC's and even though they were reasonably good quality at the extremes just wiggling the connectors slightly to vary the contact resistance (and probably capacitance etc.) a bit can make dB's of difference to the measured directivity. Thankfully this is not a big problem under normal usage. Your PL259's would probably have similar effects though possibly not quite as noticeable at the directivities and frequencies you were looking at.

Hi Ted,
No doubt, the VFO could be put on the correct freq range with C3 included-
it was just very nonlinear.

You don't say if this is on the input or output of said amp - based on
your question the assumption is input. Why do you say Chebyshev if you
don't know values?

I don't have anyway to measure the
> values of the inductors or capacitors used in that circuit. When I

This may or may not be any indication of linearity. A better check would be
to listen off channel.

I gave a presentation on "How Ham Radio Can Help You in an Emergency"
to 70 Emergency Management types last week, and the windows in the
building which hosted the meeting were NOT open-able (so I "made do"
with an inside VHF antenna and didn't even try to demonstrate HF).

But in emergency/expedient situations, it would be really handy if one
could pass at HF, say, 100 watts of RF energy through a window (I
visualize some foil strips and an inductor or two to "tune out" the
capacitance) to an external antenna.

I've been told that the April, 1989, issue of Ham Radio magazine carried
an article "Easy antenna access for urban apartment dwellers" (for 15
meters) by Bryan Bergeron, NU1N, starting on page 18.

I'd sure like to read that article; can anyone send me a copy?

Source record: 12717

Depending on the type of ceramic filter, some can be moved either up or down (yep, down) in frequency with a dremel and diamond wheel. I have done this when designing AMPS transceivers for a different frequency range (lower) when the lead time on sample filters from Murata in a different range was too long. Moving them relatively small amounts, the bandwidth stays quite close. I think I went down something like 15-20 MHz. Moving them as far as you want far may be (probably is) a stretch You are trying to go from the cellular base receive to the ham band. Depending on what the amp is between the filter and output, the amp may need some tweeking for this difference in frequency. IF you had some mobile receive (45 MHz higher) filters, going that far would be easier, but I'm sure you don't.

A Comb-line ceramic filter is a block that has holes in it. It is like a box with 1/4 wave rods in a line except the box is filled with ceramic. It is about 1/4 inch thick, maybe 1/2 inch 'high' and long enough for as many hole-resonators as it has in a line. Each hole is plated inside and is a "shortened quarter wave transmission line" resonator. The "ground" or "shield" equivalent of the transmission line resonators is the two plated sides of the block. It is filed with a high-K dielectric having a very good temperature characteristics and therefore the 1/4 wave is very short -- the virtue of these filters.
Ours typically had three poles (holes-resonators) for the receive and 5 for the exciter filter.
One end (the 'bottom' or the shorted end of the quarter wave resonators) is all metal plating and holes in a line. The opposite end (the resonator open end) has little or no plating and may even show the effects of grinding to tune it. However, some are constructed with this end mounted down and therefore covered by the mounting bracket which will probably be soldered or glued on and allow limited access. Coupling for the desired bandwidth and ripple is achieved by the spacing of the resonator-holes in the solid high-k ceramic dielectric therefore, you can't buck about with coupling and must take what you get after moving.
To move up, you remove resonator from the "open" end, shortening it. To move down, you remove small areas of the ground plating at the base of the resonator-holes. I used the Dishall method and they came right on.

If the filters are comb-line with top coupling for input and output, moving them *up* far (by shortening the resonator -- which *is* the hole), I think will be hard because you will loose coupling between resonator and coupling tab when you shorten the resonator...however you could regain coupling by attaching a wire to the coupling tab and run it down the hole (the "correct" amount) to proper get coupling back.

In an emergency I'd say... uh... just leave the window open? :-)

Over on eHam.net there's a recent article on building yourself a simple rectangular wooden panel to stick in the frame of an (open) window. You then just drive holes in the panel as needed to run cables, etc. I've even seen people who didn't have, e.g., a drill or jigsaw do the same thing using a thick-ish chunk of stiff foam (insulation material or even presentation poster board) and an X-acto knife.

But be sure to bring a hefty brick along to create the opening in the first
place :)

The OP's dilema was that the window COULD NOT open, and therefore some
way to pass RF through glass would have been Useful.

What I have done is plan ahead by drilling two small holes in the glass
and plugging them with nylon screws when not in use. That works best
on the first floor. :-)

You'd have better luck with HF than VHF or UHF making it through any solid object. I have used a homebrew mag loop in a hotel room on several ocassions with some luck..on 20 and 40.

I have a 40m dipole in my attic, and I runn less than 5w HF most of the time and I have WAS on several ocassions, I try to WAS every year.

A lot of modern buildings have glass windows which not only cannot be
opened, but which have a "low-E" (low thermal emission) coating on the
glass. This is (I believe) a very thin layer of vapor-deposited
metal.

Its RF attenuation is considerable. Some years ago, we had our house
windows (1960s-era glass) replaced with new ones using a low-E-coated
glass. A previously-workable signal path for 802.11 signals, which
got to the back of the house from an access point in the garage by
going through the garage door and a couple of exterior windows,
suddently became quite unusable - I had to install an additional
access point to cover that part of the house.

The more obviously shaded or reflective the glass, the more of a
problem for RF transmission or coupling this stuff is likely to present.

> understanding the circuitry fully, it seems to be biased "above" class

1.) First of all, the MRF454 gets very non-linear at 80 watts output if you have a full 13.6 volts on the collector. If you are running 400 watts PEP, you are certainly splattering excessively. There is doubt about that. That's just how that device is. That is why Motorola calls it an 80 w device, and why four MRF-454 will barely make 300 w PEP on PEAKS with marginally acceptable IM distortion.

2.) Second, the amp MUST have filters for each range. There isn't any possible way to have that amp meet TA harmonic specs without several switched filters. Harminc have nothing to do with having acceptable IM performance.

3.) How it sounds on frequency, or how a few people tell you it sounds, has little to do with legal linearity and splatter. There isn't a person alive that can tell if an amp has unacceptable bandwidth unless he knows how to tune your signal, has a good noise environment, and your signal has acceptable strength. How you sound "on frequency" does not indicate at all how clean you are with IM distortion or splatter, and anyone checking you off frequency has to have a low noise floor, good receiver, and know how to do it.

I hope this helps. It's very important to know what we are doing with amps and radios!

Bands like 20 meters are just getting ruined by cheap 12 volt solid state amps. Well designed solid state amps are generally bad enough, but the poorly designed CB amps using transistors with poor bias systems and driving the devices into non-linearity are ruining many crowded phone bands.

If a solid state amp will run 150 watts peak power, it is generally only acceptable to 100 watts or less on peaks for SSB. The general rule of thumb for solid state amps is they have acceptable linearity only at 66 % of maximum peak power.

This is why most solid state 100 watt radios will run 150 watts when people turn up internal controls without regard for bandwidth, and why your MRF454's will run a bit over 400w saturated peak power but only be linear to about 300 watts on peaks when power is measured on an accurate peak meter.

>what you guys find out so far?

The fact that you can persuade the radio's synthesizer to tune
frequencies outside of the 2-meter band, does not mean that either the
transmitter or receiver circuitry is necessarily going to work well on
those frequencies. The transmitter circuit is very probably "tuned"
for operation in the 2-meter band, and forcing it to operate outside
of its tuning range will probably result in degraded performance.

The radio almost certainly has a low-pass filter between the RF
module and the antenna. This is necessary in order to keep
the radio's transmitter from emitting spurs or harmonics in
excess of the FCC limits. This filter is likely to "roll off" any
transmissions above the 2-meter band to some extent, and (if it's in
the receive pathway) will probably reduce the received signal
strength as well.

It's even possible that transmitted at such a high frequency might
damage the radio's power amplifier... the amp's likely to be looking
into a severe impedance mismatch and the high SWR might overstress it.

You don't say where you live, but you should be aware that here in the
U.S. it's illegal to transmit outside of the 2-meter band with a radio
modified in this fashion. Google for "Jack Gerritsen" to understand
some of the potential consequences.

Even in an emergency situation, I just don't think it would be a good idea to string some kind of an antenna above the heads of shelterees and then start soaking them with RF, especially depending on the HF frequency in use. In fact, I suspect the FCC's RF-exposure regulations would frown on one doing so!

Some of the third party replacement antennas were made with military
surplus RG62, and had hand soldered motorola plugs instead of the OEM
crimped plugs. I cut up a lot of old antenna cables and stripped the
copper braid to use as solder wick by dipping it into liquid rosin. Some
had the plastic spacer for the center conductor, but most didn't. Some
weeks we replaced a half dozen car radio antennas, so I always had
plenty of copper braid at hand. years later I worked for a CATV company
repairing converters. The braid from the control cables was a little
under 1/8" when it was pulled tight and flattened by pulling it around
the blade of a screwdriver.

Hi gang,
I know there are a number of people on this list who work in 2 way and

other RF fields. I used to, but have been out of the loop for a while
so I need your current expertise.
Specifically, I need to determine what transmitting type services
currently (or may soon) use amplitude modulation of the radiated signal
in the 80MHz to 1GHz range. In my day it was restricted to aircraft
comms in the 108MHz to 138MHz range and the video carrier of broadcast
TV. Is this still the case, or have things changed? I don't need to
know about 'closed circuit' paths such as cable TV and the like, only
services that radiate RF.
Also, if anyone has any knowledge of the general picture of frequency
allocations in the same range quoted above in Europe and Asia, I would
appreciate it.
Thanks a lot and please respond off list.

New program LINE_ZIN, for given frequency and load impedance, for
balanced-twin lines, calculates -

Impedance Zo
Input impedance, R+jX
Attenuation, dB
Power efficiency %
Loss with standing waves, dB
Reflection coefficient
Angle of refl.coeff.
SWR at load end
SWR at input end

Input data can be varied in small increments from the keyboard to
observe how a line behaves. Practical and educational.

Download program LINE_ZIN (40 K-bytes) in a few seconds from website
below and run imediately.

I do not have the article but one solution that was proposed and tried worked great. Use tinfoin and rubber glue, cut the tin foil to fit the glass. Apply rubber glue to hold the foil to each side of the glass, Thickness of teh glass is not important. In my case I used the metal frame of the glass to carry the gound signal through the window frame. I then used an antenna tuner to adjust out the capacitor I just created. Worked great, no drilling no running coax in and out so I can close the window etc.

Source record: 12735

I have been characterizing some of the new Mini-Circuits LAVI-XXX series mixers. These devices have an IP3 in the +35 to +40dBm range. Using HP 8644 signal generators to characterize IP3, I was only able to achieve +33dBm.......IP2 was only in the low 60s. Return loss at the RF and I.F. ports was only measured at 12 to 13dB.
I spoke to Mr. Lu Chen at Mini-Circuits and he explained that all sources must have all harmonics down by at least -65dBc, and that the 6th and 9th harmonics of the LO can be especially troublesome in degrading the performance.
Using a low-pass filter on the LO improved the return loss to 20dB, while the IP2 improved to +72dBm and the IP3 improved to +40dBm. It is always good to have a clean LO source. If your 2nd harmonic is below -25dBc and higher order terms are below -40dBc, you will have pretty good performance from the receiver. A low-pass filter ahead of the 1st mixer will help reject that 90 to 120MHz image band.

Perhaps.

In an emergency situation though, you do what you need to do and try not to let the regulations keep you from saving lives and/or property..while still keeping the regs in mind.

When I use my portable mag loop for 20 and 40, from my hotel room, I try to place it outside my room...but that hasn't always been possible. At my low power I would have to guess the RF I'm bathing in should only be slightly more harmful than the X rays leaking out of my cheap "Made in Turdistan" TV set. I certainly wouldn't attempt using this setup with much more than a few watts of power.

As for my attic dipoles, I have never tried to measure the exposure level in my home. I'll check in to that..but again, at 5w or less it can't be too dangerous.

Hi.

I am building an amp and will be using a clear plastic over the front panel graphics.

I could use some help in choosing the material, such as Plexi or Lexan. Since I will be drilling couple of 2" holes to mount panel meters, I need some suggestions for which material is the best to work with. A hole saw in Plexi is prone to crack and maybe there is a better choice. There also may be a better method for creating the holes than a standard hole saw. Suggestions???

==========
Might be OK for single - ,but NOT for double glazed windows.

A solution for HF 'might' be an inductive coupler/matching unit , with
half of it including an inductor on the outside with the other inductor
and 'tuning bits' inside .Both inductors 'in-line' for best possible
coupling. If an outside variable capacitor is to be used ,its shaft
could possibly be magnetically coupled with a manipulator fitted inside
,using strong magnets .
Home-brewing Ham Radio equipment is and remains an interesting
ideas-provoking activity .

Hi Rick,

Lexan has a higher melting point than Plexi. Therefore it's easier to drill or cut. Plexi tends to stick to the drill bit once it becomes hot. Lexan is more robust from a mechanical point of view, while Plexi tends to break. So if you have both available I think Lexan is the better choice.

In my experience...Lexan is much less prone to cracking but on the other
hand it seems like the surface of Lexan scratches much easier than
Plexiglass. A wipe with a dry cloth or paper towel will leave a 'smudge
If you're gonna use a fairly thin plastic, say 1/8th, I think you'd be
ok with plexi and thats what I would use personally because of that
reason primarily. Some of the cheapo hole cutters can be rather crude
to work with but if you take it slow you should be ok.

KJ4UO-

If you don't find one, I suggest you "reverse look up" the original part number. (Could it be a Fairchild uA736? A National Semiconductor LM736?)

In other words, you may have better luck finding a data sheet for the original manufacturer's part, and trusting that the ECG/NTE part meets the same specs.

Wow, getting fancy! All my homebrew amps have front panels that are so primitive, stone age carving in tablets would've been one step up from them :-).

> I could use some help in choosing the material, such as Plexi or Lexan.

> Suggestions???

A coping or hacksaw can be used instead of a hole saw. Motor-driven saws like bandsaws or jigsaws, I'm not going to say it's impossible to get good results with them, but I have never had good luck. It's only a couple of holes and soft material so a handsaw will work fine.

Plastic shops and fabricators have special-rake drills and hole saws that make putting holes in plastic sheet much much easier than attempting to use regular metal or wood tools. If you have a lot of little holes, you definitely want to buy the plastic-cutting drill bits for those sizes. If you only have a couple of 2" holes you'll probably have a hard time justifying buying a special plastic-cutting hole saw for that size.

Regular metal and wood tools can also be reground to be less likely to crack plastic sheet. The plastic distributors have little pamphlets that explain the how-to. I have not found this information on a website yet.

For any cut where you can see the edge, you then go back and sand/buff/polish to make it look nice and clear and shiny again.

Tim.

Lexan, being polycarbonate, is much tougher than Plexiglass, which is acrylic. Ploycarbonate is used in everything from RC car bodies to soft drink bottles to bullet-resistant windows in aircraft.

First you should follow all recommendations from your supplier. In

addition, you should use plenty of lubricant, or better lubricating coolant. I'd flood the thing, and use really slow tool rates (i.e. use your drill press with the slowest gearing).

rec.crafts.metalworking has some folk who will give you good answers, if you don't mind sorting through all the political chaff.

Why not just use acetate sheet to cover the panel. Like what is used with
overhead projectors. If it is just to protect the graphics and not for
mechanical strength that is. Jtt.

or just put a good coat of clear lacquer over the front panel graphics

When I have needed to cut holes in plexi in the past, I always created a plywood / plexiglass sandwich. Just place the plexiglas betewwn two thin sheets of plywood and drill thru the whole thing with a hole saw.

On the other hand, you could just mount the plexiglass on top of the meters, this would protect the meter faces from scratches also. This way, you only need to drill holes for switches and knob shafts.

Depress the PTT, then just chatter away with mouth 3-4 inches away from mike If this doesn't penetrate the glass,.....check the battery. This should make it through the window pane, however, in the event it doesn't make it through put a through-the-glass-connector on, this capacitive mount outa do it, however, ife'n it don't, shoot it with (the radio) a .22 calibre / caliber (spl chk lists both, I have a very expensive spel chk or a very cheap one that really doesn't know how to spell calibre anyway)pistol which should should disable the broken little piece of crap. If RF made it through before the .22 killed it (if in fact it actually did)load up a 44 magnum 180 grain hydroshock bullita, TexMex pronunciation, be carefull with this one, it'l hurt 'ya big time. Be sure to place this shell into a 44 calibre/caliber fram designed for this shell Like I shoulda said before (this is the disclaimer) you cannot just put the 44 shell in just any 44 frame, ...now shoot the window this time, it should pass rf, if not you probably killed a perfectly good transceiver because you didn't know whut you were doing. Sorry 'bout that rig man!

ECG published a set of three databooks about 20 years ago that
covered their current product line. My set disappeared about 15 years
ago. You might want to keep an eye out for a set of them.

I have drilled a hole in a window frame and passed a piece of RG-58 through
it. A 2M rig in my den is that way right now. It's easier to justify doing
it to your own home than to a place you're visiting

No, you don't keep it in a "bath" of kerosene. Just take an eyedropper containing kerosene and put a few drops right where the drill contacts the glass. Replenish as needed.

2 thoughts

1. If you decide to use the plastic water with a bit of detergent
makes a good coolant/lubricant. Keep the cut flooded.

2. I made a lot of panel covers inthe past by laying out the panel in
Autocad then flipping the drawing layer with the graphics on it to get
a reverse image. I then made an overhead transparency of the graphics
and used the transparency over the metal panel. The result was a clear
plastic cover with the printing sandwiched against the metal panel.
It worked quite nicely. You might want to consider it.

Whats the context of the question?

I doubt there are too many new AM applications, however if you are concerned about the envelope of an emission for EMC concerns, Quadrature Amplitude Modulation (QAM) is a form which includes "AM". Also Time Division Multplex (TDMA) signals rapidly switch from an off to on state. There are also On Off Keying (OOK) schemes used by remote control key fobs and garage door openeres.

Let's talk methodology in the cutting of a decently clean hole. Get a piece of plywood that is slightly larger than the piece of plexi or whatever you are going to work on. Get a couple of C clamps also. Now, lay the plexi on top of the plywood, and clamp the whole thing onto the workbench with the C clamps. (This is why it's better to cut the plexi to size afterwards, since you will have an extra edge to clamp to, so you dont care if you mar it with the clamps.) You can then drill the holes fairly accurately, without making a big mess. Stability of the work pieces is of paramount importance here, if you want a quality job. Another trick commonly used in the woodworking shop to reduce rough edges around the hole is to lay another piece of plywood on TOP of the plexi before drilling it. This reduces the "tear out" and melting around the edges of the hole. Drill small 1/8 inch guide holes in the exact centers of where you want the holes FIRST. This will tend to stabilize and center the hole saw when starting the hole.

If you have a router and circle cutter attachment around the shop, then you can neatly sidestep the entire "hole saw and driill" debacle, since the router, with a straight bit , will cut a MUCH cleaner hole than any hole saw.. Just drill the centering holes, and put the circle cutter on there, and cut the hole, routing out about 1/8 inch of depth on each turn. No burning, no melting. (Clockwise rotation, please) The same discussion on clamping applies here, also. The difference here is that you dont have to apply any pressure to the router when cutting, like you would with a hole saw. The router actually cuts the material out of it's way as it goes. Very little, if any, dressing of the hole edges will be needed afterwards.

O yes...

For Linux?

Try Splat.

However, It looks like there are a lot of converted Unix
programs that now run on Linux.

For Windooze?
It looks like many (most actually) are commercial
programs only.

Cheers

Having the sheet of glass submerged while drilling dampens out the shock
waves and helps to prevent shattering.
However, I don't see what the special attraction would be for using
Kerosene. Plain old water works just fine. Just make sure you use the
correct type of drill bit and a nice slow cutting speed.
Kerosene is not significantly more viscous than water, so if you want to
really damp things out I'd use a heavy grade lube oil, maybe a 20-50
grade motor oil. Far less flammable, as well.

My experience with Lexan is that oils and/or solvents will cause it to
become very brittle and crack at any machined edges, including drilled
holes.

A necessary preface.....

(It is becoming increasingly difficult to fly the flag for
decency and for civilised behaviour in Radio Hammery. Even
the Usenet newsgroups dedicated to the cause have degenerated
into a hotbed of abusive onslaughts by those who ought to know
better; the Nugatory Numpties who boast of an interest
exceeding 10, 20, 30, 40 or even 50 years and yet who have
proved themselves incapable of even meeting the trivial exam
standards set for 6-year-olds. However, there still exists
the fundamental basis on which Ham Radio is based, and
that will never die. This FAQ ("What Is Ham Radio?") will
be regularly published and will not be shouted or bullied
down. It is important that those of a technical bent, who
are the natural seed-corn of Radio Hammery and who
gravitate towards us to be the real novitiate, can
still find us, (and know that we are still here), their fellows.)

-----ooooo-----

So,.....What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams

are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that

such a licence says no more about him than having a land-line telephone, whilst continuing to regard Ham Radio as a separate technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between a Ham Radio licence and a CB Radio licence. To him, they are sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then tries to classify himself as the equal of the Radio Ham when, in fact, he is nothing of the kind.

Ham Radio is not CB Radio and has no common ground with it! Ham Radio is _THE_ technical pursuit for gentlemen; CB Radio is the operating hobby for those who buy their rigs and equipment off the shelf.

-----ooooo-----

If you are the sort of person who is motivated by a technical interest in how things work; if you took apart malfunctioning clocks, toasters and the like and put them right despite never having seen them working, then a Ham Radio licence is your traditional route! There has never been a shortage of such people, and those who gravitate towards such an interest have always been welcomed into our shacks and their interests fostered. There is not today, nor has there ever been, a need to go out and encourage and press children, children who have never expressed an interest in Ham Radio, to come into our shacks. Such an activity should cause eyebrows to be raised - what normal well-adjusted adults seek the social acquaintance of children?!

-----ooooo-----

Please remember that this FAQ is a _POSITIVE EXHORTATION_ to you to exert yourselves to join our fraternity! (If you find otherwise, then perhaps you are already classing yourself in the mediocre groups of those who are criticised in the FAQ and from whom we _MUST_ dissociate? If so - it's never too late for a re-taxonomisation on your part - there's nothing elitist about us, and we welcome all those who are prepared to put themselves out in order to join our ranks!)

The _easy_ way to drill glass is to use a piece of copper tubing with
hole-size for its OD, some powered carborundum as an abrasive, and
just enough water to keep it in a slurry. Use a drill press, low
RPMs, and light pressure.

For the US, there are two. Nuts and Volts (www.nutsvolts.com) and Make.
Make is a new magazine from O'Reilly, the computer book publisher.
It's only a year or two old. (Saw it at the local Barnes and Noble.
A rather expensive quarterly, as I remmember). Circuit Cellar Ink
probably could qualify, too, but it's more of a pro embedded microcomputer
hardware/software mag.

Myron,

I built a set of tuned rings to couple a 4MHz signal from an ultrasound transducer to its processing/signal generation box. I used a small copper ring (only about 6") split at one point with a resonating capacitor across the gap on the ultrasound box side. The coax was connected across this gap also.

On the transducer side, use an identical loop and capacitor but make a series resonant circuit (capacitor in series with one of the feedline leads). Loops were separated by about 1/4 inch.

I know this configuration (parallel resonant on the transciever side, series resonant on the "antenna" side) worked the best.

It worked well in terms of passing the signal through undistorted (looked at amplitude and phase on both sides of the circuit, only got a bit of a phase shift, no amplitude loss)

I don't know about power handling. If you use hefty capacitors, there should be no problem. Bandwidth could be quite low with high-Q circuits, but maybe you could use variable caps.

I think your idea with capacitative coupling with inductors to tune out the reactance would work fine too, but I haven't tried that.

Anyway, the inductive thing works OK. I got the idea from a older (1950's?) ARRL antenna book that touted it as a way to allow rotation a parallel-line fed beam.

You'd certainly need a set of coupling rings for each band of interest, or switched or variable capacitors.

Low E glass would get some eddy currents going. I don't know how conductive it really is though, so ... who knows?

If you do try that, I recommend keeping the Q as low as possible. Otherwise, voltages will get very high, and you might well end up with greater loss as well as other problems. Minimizing the Q means keeping reactance values low which in turn means making C as large as possible. This leaves you with less reactance to compensate for. In other words, don't make the C small and try to compensate for the large amount of resulting reactance.

2284. More solid state HF amp questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-11 02:35:07 UTC
From: KC2PIH@gmail.com
Message-ID: <1144722906.952730.211040@v46g2000cwv.googlegroups.com>
Source record: 12683

Hello!

Alright this is my second post on this subject. I appreciate all the other responses I got. I don't think I provided enough information about my problem before. So here it goes with everything I've got. I picked up a HF amp that has four Motorola MRF-454 transistors in it.

I've already determined (in theory) to make it run "clean" enough, I'll have to build a band-switched filter bank for it. It already has a 5-element Chebyshev filter
in it and I am guessing that its tuned for 30Mhz. Also, it shouldn't be driven over about 300 watts (output).

Though I do still have a problem with it and this is what this post is about. When the input power to the amp goes up, so does the SWR. I wasn't able to test it with access to the amp's components when running to check for components heating up (as somebody already asked about). You can see it has some swamping resistors to reduce drive power - keep in mind these readings are taken with all the resistors bypassed (meaning input power to amp is not attenuated). It has a receive pre-amp and a carrier operated relay circuit as well.

Here is what I see:

Configuration:
[FT-890] -> [SWR/Power Meter] -> [AMP] -> [Dummy Load]
(Power listed is the output power from the radio, driving the amp)

Frequency Power(input) SWR

3.900 5 1.8:1
7.200 5 1.6:1
14.20 5 1.6:1
21.20 5 2.7:1
24.90 5 1.7:1
29.99 5 1.0:1

Frequency Power(input) SWR

3.900 10 3.0:1
7.200 10 3.0:1
14.20 10 >3.0:1
21.20 10 >3.0:1
24.90 10 2.9:1
29.99 10 1.3:1

Frequency Power SWR

3.900 15 >3.0:1
7.200 15 >3.0:1
14.20 15 >3.0:1
21.20 15 >3.0:1
24.90 15 >3.0:1
29.99 15 1.5:0

SWR between the AMP and the Dummy Load is perfect in all cases (dummy load rated to 670Mhz). Amp output power goes up as frequency goes down (with constant drive), so I guess this amp doesn't include anytype of network to normalize the gain of the amp across the HF band. I actually tried a couple radios (FT-890 and the FT-100) to make sure the radio wasn't the cause.

A picture is worth a thousand words. Pics (1600x1200 High Resolution):

You could well be correct on this, as the lighter weight solvents will have a detrimental effect on the surface of Plexi, etc. I was referring to the comments related to glass, which is not affected at all by such things.

==========
Would a high voltage switching transistor with/without an opto-coupler
circuit not be more reliable ?
The opto-coupler circuit can be tailored for the transceiver's output
and a cheap High Voltage transistor could excite the amplifier.
Just a thought.

Frank GM0CSZ / KN6WH

I have read your article with great interest.
Do you have a specification for the "balun formers" or maybe a Rockby
Electronics stock no.?
I suppose it is www.rockby.com.au. The only 2-hole ferrite core I could find
is stock no. 10967 but I believe this one is too small.

Anybody built a regenerative receiver (tube or MOSFET :) using
oldschool spider web coils ?
In theory they have a very low amount of parasitic capacitance, and a
high Q.
Is it worth to use them for amateur bands ?

I've built some some for general coverage use. No problem getting them to work.
http://www.sparkbench.com/swsw.jpg
If there's a complaint to be found it might be that they wouldn't be as thermally stable as a nice tightly wound coil on a form. In my case I used them in a general coverage (0-100) receiver - for a ham band receiver they might be a little sloppy. You also lack the ability to "fine-tune" them the way you can with a solenoid coil where you can squeeze/strech the turns.

Does anyone have the assembly instructions (file, link or just the dimensions) for the UG536B/U Straight N type plug for RG58/U cable ? My web searching efforts have yielded nothing (it's a bit obsolete). I'm trying to make up a cable for 2.3 GHz so I would like to get the dimensions right in the hope of getting a half decent match.

That part is an Amphenol P/N 34025-RFX.

Go to:

http://www.amphenolrf.com/search_2_results.asp

and click on "Assembly Instructions"

BTW, it doesn't seem to be obsolete. Click on "Distributor
Inventory" for a surprise. :-)

Hmmm...

It appears the RG536B/U is an Amphenol 34025, which has different
cable prep dimensions from the 34025-RFX.

Source record: 12602

3a. Tune (match) the input for lowest in-system noise figure.
This is in general not a match for maximum power transfer.
3b. Be sure the active device(s) is/are biased for optimum
noise figure: collector/drain voltage and standing current.
4. Be sure there are not any unnecessary noise
contributions from components other than the
active devices in the amplifier.
If you want to consider the system as a whole,
4. Lower the loss between the antenna and the preamp
(eliminate feedline, for example).
5. Be sure that the preamp has enough gain that it
sensibly sets the system noise figure. (Be sure
that its gain gets the signal seen at the next stage
high enough that the next stage contributes
insignificant noise to the system.)
... etc.

But beware of trading other things for noise figure: beware of
poor intermod or desense performance, for example.

Cheers,

I wish !....hmmm, no I don't. That would be terribly difficult to tune.

> Did you observe increased effect of hand capacity or it has nothing in
> common with that kind of coils ?
>

No. If anything the hand effect is decreased since its not "360 degrees" like a typical vertically mounted solenoid winding. Of course that depends on the placement of the hand, doesn't it?

I think you should try it. Its easy enough to do - and looks cool also. I can't think of any other reason to do it that way. At SW freqs I suspect the Q is in the same range as toroids or regular coils. I have some specific uh/turn numbers for the spider size that I used if you are interested.

As a point of reference, a typical NE3508M04
(http://www.cel.com/pdf/datasheets/ne3508m04.pdf) can give you a device
noise figure under 0.4dB, operated at room temperature, at any
frequency across the entire "UHF" frequency range (300MHz to
3GHz)--better than that at the lower end of the frequency range.

Question ; Would it be sensible to use RG58/U for 2.3 GHz sig (obviously
depending on length of that type of coax) I thought teflon type coax was
almost mandatory for that frequency.
Just curious , wishing to learn .

Not really, but it is what I have available at present ! Teflon vs polyethylene isn't reallly that important with regard to frequency...it is more a question of quality of the shield, I think. I suppose polyethylene insulation will tend to melt while soldering connectors so it is more likely that an impedance bump will occur due to the centre conductor being off-centre. Non-solid insulation would have less loss but this has to survive being passed through car-door seals.

It is probably a good thing these things have been discontinued, too. I found it impossible to assemble without special jigging to prevent the insulation from melting and swelling up while soldering the pin, blocking the assembly. Teflon insulation would behave better I suppose.

With one end kluged into shape with a hot knife and the other end soldered with the insulation wrapped with aluminum tape, the return loss of the cable and a good load measures around 27 dB or better (probably beyond the accuracy limits of my test setup), so they work OK regardless of the kluges.

Thanks Steve for the above . Unless 50 Ohms coax is absolutely
necessary , you might wish to consider 75 Ohms coax as used for domestic
satellite receivers (between the rx and the converter,also called
LNB=Low Noise Block,located at the dish). That type of coax is double
screened with both braid + copper foil and would be superior to RG58/U
coax. It is fitted with socalled F-connectors ,without having to solder
since the solid copper core serves as centre pin. I have been able to
purchase F to N-male adaptors and by using an additional double F-female
union ,this would possibly solve your problem as well .
Sat receivers normally have an input signal between 950-2150 MHz ,with
the dish converter subtracting 10 GHz or about from the actual satellite
signal received .

Well, yes, I can certainly believe that you've messed up the match by removing that part. If you can identify the active device, maybe you can get info about it and use that to design a proper match for low noise. Otherwise, I suppose you can make some educated guesses about a matching network that does the right job. I gather you are not trying for an extremely wide bandwidth, so a matching network with not very many parts should work OK. At a single frequency, it should always be possible to design an "L" network to do the job, and if the impedance ratio from input to output isn't very large, you'll get very decent bandwidth: low Q.

Beware of stability in the amplifier, too...an instability could really mess up the noise figure.

Hope this all makes sense...

Cheers,
Tom

2313. Source of info on old transistors

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-13 03:25:44 UTC
From: Ronnie <rhughes4-removeme@swbell.net>
Message-ID: <Ywj%f.58555$F_3.14821@newssvr29.news.prodigy.net>
Source record: 12614

Hi,

Anybody have a library of transistor databooks
from the early 60's? I'm trying to find technical
info on the following devices:

Power Transistors:
Motorola 48S23 in TO3 Steel case

Signal Transistors:

Motorola 48S45 (624 date code or other marking)
Motorola MA900 (Sort of crossed to NTE 102A or ECG 102)
Mototola SM1824 (612 date code or other marking)
(one schematic I have shows this to be a
PNP type)

2N1192 (Schematic shows as PNP type - one hit shows as
Germanium)
Motorola SM2140 (Schematic shows as PNP type)
GA987 (980425 date code or other marking)

I'm unsure about the manufacturer of the last device. All the other have
the Motorola circle M logo clearly marked, but it is not on that device.
The system these devices are in was manufactured in the fall of 1963
so it is likely that the deisgn is from the 1960 to 1962. I'd like to
browse
through a 1960 to 1963 Motorola data book. I'm suspecting all of these
to be PNP type Germanium devices, but that is just a guess.

Any help appreciated.

Ronnie, N5CSE

2314. New program. COAX_VLF

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-13 04:45:00 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <DMadnQ-pGKIMSqDZRVny2w@bt.com>
Source record: 12615

Now available: Program COAX_VLF

The behaviour of transmission lines at the lower frequencies is more complex than it is at HF and above. The effects set in sooner at higher frequencies on low impedance coaxial transmission lines. They are affected more at higher frequencies than other types of line.

As frequency is reduced below several hundred KHz the impedance Zo increases, its impedance angle becomes more negative, and the propagation velocity decreases. Unusual things happen such as reflection coefficients being greater than unity and the SWR being greater at the input end of a line than it is at the load end.

At power and audio frequencies Zo can be an order of magnitude greater than the nominal HF value, and the angle of Zo aproaches -45 degrees.

It is useful to be aware of the magnitude of such effects. With coax they can be experienced in small ways at frequencies as high as 2 MHz or more.

Download program COAX_VLF in a few seconds from website below and run immediately. Filesize = 48 Kilo-bytes. It is both practical and educational. Try to fathom out how reflection coefficients greater than unity can arise.

Maybe not worth reading, but in the late 1940's I used a single 01A
regen with homemade spider-web coils on the broadcast band. Probably was the
root factor for Ms. Farnham kicking me out of high school Latin class. (for
sleeping when I was supposed to be listening). From Washington State, XERF
in Warez, Mexico came booming in until the wee morning hours. Oh, for the
days of snake-oil medicines and Bible thumping!
Technical notes: I did find that to find the best orientation for the
antenna (with tickler) coil was critical. Using common masonite front panels
ment that hand-capacitance greatly affected the amount of regeneration.
Usually just left the coil flopping on its leads until the best compromise
position was found, then invent a bracket or sticks and glue to hold it in
position.

With the exception of the 2N1192, most of your numbers don't sound like
Motorola numbers.

It may be that Motorola manufactured standard parts for a company, and
marked them with that company's proprietary numbers instead. Under their
agreements, Motorola is unlikely to provide any cross-reference
information, requiring you to purchase replacements from the other
company. Even other divisions of Motorola did this!

There may be some cross-reference information, but it would help to know
the manufacturer of the equipment the Motorola parts were used in.

Have you tried a Google search for each of the numbers?

Hi Doc:

I bought a good 898 recently for £30 which I guess is around $44.

Ronnie,
I concurr. Those (non 2N numbers) are not "public" numbers, but
"in-house" numbers belonging to the original equipment's manufacturer. I
have some old references, but there IS stuff on the web.
AllDataSheet gives some specs on the 2N1192:
http://pdf1.alldatasheet.com/datasheet-pdf/view/120668/ETC/2N1192.html

Alloy Junction Germanium Transistor
PNP 200mw.
40 V Vcb
25 V Vce (R) whatever that means
hfe 74 typ
2 MHz Ft
TO-5 case

Im guessing at the noise figure, im running a low level >1mv fr0m a
cushman service monitor to the preamp input. Im using a uniden 898t
scanner as a receiver because it has a digital S meter. When i turn on
the preamp jumps up 3-4 bars
but the modulation tone stays the same volume level. By this im
guessing the noise level has increased, the preamp had a ceramic
filter with the 50ohm input going directly into it and its output thur
cap to the 1st amp, the seller on ebay said just remove the filter and
move the input to the filters output trace, thats what i done but
results are poor even thou this is a commercial preamp pulled from
analog cell site. It looks to be a very well made preamp so it should
work if i figure out the
input match?

The device in the preamp may not have the greatest noise figure to start with. Most preamps used in those type installations are usually more concerned with signal handling ability, so as not to produce intermod, rather than the last ounce of signal to noise performance. It is difficult to have a device that will give you maximum signal to noise performance along with excellent intermod performance. Often a preamp is used ahead of power dividers to feed several receivers and it is there to make up for the losses in the power dividers and not necessarily there for the sole purpose of improving signal to noise performance.

When comparing how it is performing you need to actually measure sinadd or quieting of the receiver to tell if it is giving you any improvement. Just looking at stronger noise levels on the receiver and guessing how much the signal is above the noise can be very misleading.

If your modulation is FM, the receiver audio is going to remain the same. And yes, the S meter will jump due to excess noise output of the preamplifier. The Excess gain will reduce the dynamic range of your receiver system and cause intermodulation (IM).

1. Connect a SINAD meter to your receiver .
2. Connect the Cushman directly to the receiver, adjust for +/- 3.0 KHz deviation with 1000 Hz tone.
3. Adjust Cushman generator for 12 dB SINAD
4. Note the generator output in dBm
5. Install preamplifier between Cushman and receiver
6. Adjust generator again for 12 dB SINAD
7. Note the generator output in dBm (should be more negative value than step 4)
8. The difference in dBm from steps 4 and 7 relate to the improvment (if any) in noise figure between the receiver alone and the receiver with the preamplifier.

9. Install a variable attenuator between output of preamplifier and input of receiver. Set to 0 dB attenuation.
10. Adjust generator for 12 dB SINAD
11. Adjust variable attenuator from step 9 until the 12 dB SINAD degrades slighly (numerically < 12 dB).
12. Readjust attenuator 1 dB per step until 12 dB SINAD is restored.
13. You have optimized your receiver and preamplifier for best intermodulation (IM) performance.
14. Install preamplifier close to antenna with a feedline, replace variable attenuator with fixed value equal to the value from step 12 minu the measured loss of the feedline between preamplifier and receiver.

15. If Cushman doesn't display dBM, use microvolts, fewer microvolts for 12 dB SINAD is the goal!

16. The above assumed an unmodified, properly operating preamplifier. Your preamplifier must have some sort of preselector filter between the antenna and it's input. Removing the stock filter exposes the preamplifier to overload from out of band signals, may affect the impedance (stability) of the preamplifier. Try operating it in its stock configuration and frequency prior to modifieing it. Then replace the stock filter with a properly tuned filter for the frequency you desire. Yes, you might have to retune the preamp if the frequency change is too far. Use the SINAD method and a low level signal to tweak the preamplifier sensitivity. Make sure your generator and cables are 50 ohms. A 10 dB 50 ohm pad between generator output and the system, may improve your results if the generator does not provide a 50 ohm source.

300W That's absolute peak output, which you could see on a true PEP
meter.

Yes, it looks like the filter is tuned for 30MHz. The amp might or
might not work OK on lower bands with a proper filter. You'll just have
to try it.

I'd check it very carefully for splatter on SSB, and for parasitics and
other spurious. But the SWR increase you see could just be because it
has no filtering.

As Fred and Steve noted, you have a bunch of "house-numbered"
transistors, and one that's relatively easy. Actually, the MA900 seems
to be from a series of germanium parts. I have numbers on both sides
of it, but not that particular one, in my book. I do have a full
Motorola data sheet on the 2N1192, in my 1969 Motorola "Semiconductor
Data Book." Since I'm about to scan something else, I scanned it into
a PDF (as images, not text). It's not great, but it's legible. Email
me if you'd like a copy.

Cheers,
Tom

Christer,
It looks like Rockby has sold out and removed them from their catalogue, the one you pointed out is indeed not the correct part. The ones I used are as far as I know a standard/common 14mm balun former as used in TV baluns etc..
The Jaycar (www.jaycar.com.au), or Electus (http://www.electusdistribution.com.au) part number LF1220 looks basically identical to those I used, and there are probably lots of equivalents out there. Electus has some data on the M7 material used here http://www.electusdistribution.com.au/images_uploaded/ferrites.pdf
I hope this helps, and I would be interested in how you get on if you end up building one, let me know at the email address shown below.

Your best source of information here will be the manufacturer.

Next best will be to put a test object (made of things that don't absorb microwaves) glued with the epoxy in your microwave with a cup of water and heat it until the water boils. If the test object isn't uncomfortably hot, the epoxy probably is OK for use in your quad. Microwave ovens here in the US seem to run around 2.45 GHz, which is fairly close to your working frequency, so the test will be a fairly good indication.

Thanks Fred, Steve, Tom:

I think you guys are correct about these being house numbered devices. They are from an old Piper autopilot that was manufactured for Piper by Mitchell Industries of Mineral Wells, TX (now Century Flight Systems). I noticed that 2 of the 12 power transistors had been replaced at some point in time and are marked with "Mitchell Industries MN92". Since this was an avionics application, it is likely that these were marked specifically for Mitchell, initially with the 48S23 device number and then later with Mitchell's name and MN92 marking.

I've made an attempt to see what information Centrury Flight Systems is able and/or willing to provide, but so far they have not been too responsive. I'm also looking for a spare amplifier from the aircraft salvage yards and avionics shops.

My main interest in all of this was to generate a schematic of the amplifier and do a bit of reverse engineering in order to better understand the overall design of the system. The service manual for the autopilot system did not include a schematic or any details of the amplifier.

Thanks again for the help.

Ronnie

Source record: 12635

>From that era, and from what you know so far (that they are apparently pretty much all germanium parts), it shouldn't be too difficult to deduce how it worked. It's unlikely any of the active parts are particularly esoteric. Usually you can figure out the polarity of the parts from the schematic, and assuming about 0.3V for forward junction bias and current gains typical of the power and signal transistors then in use should get you close to what you need. I suppose nothing in an autopilot needs to be very fast, so it's very unlikely any are RF transistors. It's possible that the circuit requires close tolerance on some feature (like gain), but that's poor circuit design and I'd hope for better of them. Once you have a circuit diagram, maybe you could try "spicing" it, if you're not comfortable with a simple paper analysis.

Good luck with it.

Cheers,
Tom

2335. freeware for determining mixer products?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-14 15:29:59 UTC
From: Mike Rhoads <a@b.c>
Message-ID: <XdP%f.6978$i41.2958@newsread1.news.atl.earthlink.net>
Source record: 12636

I have a receiver I am considering modifying for other bands outside of what it covers. It is a dual conversion superhet design. Before I modify it, I'd like to see how the new frequencies would affect the mixer output. Is there any decent freeware available that would allow me to see all mixer outputs and to determine if any outputs might be a problem?

Thanks,
Mike

2336. Re: Source of info on old transistors

Message-ID: <oKP%f.10837$4L1.4249@newssvr11.news.prodigy.com>
Source record: 12637

Tome,

I agree with all you've said. In general the autopliot
amp is a DC circuit and has a slow response time.

However, this system does generate RF signals which
are used to sense the pitch and roll attitude and the postion
of the servos.

This autopilot system uses variable inductors to sense pitch
and bank information from the attitude gyro. Each one consists
of an iron and aluminum metal vane attached to the corresponding
axis of the atitude gyro which moves in front of a iron core coil as a
pick up. I found a test box designed for the system that includes a
jack that provides a dummy AI gyro allowing the substituion of its
inductors in place of the actual gyro for bench testing. It contains
standard looking RF coils with tunable slugs.

The service manual states an operating frequency of 10 MHz, but that is
stated only as an exmaple. I'm not sure it that is the actual freq or not.
The resonant frequency is determined by the inductance in the AI gyro,
air variable caps in the servos and some variable air caps used for trim
and centering adjustments. The circuirt is arranged so that as the airplane
changes pitch or bank, the changes in reactance cause the circuit to change
frequency. A discriminator in the amp detects the frequency change,
produces
a DC voltage which is amplified to drive the servo motor in the appropriate
direction to bring the circuit back into resonnance via the feedback caps
that sense servo postion. This or course moves the control surfaces and
brings the airplane back to level flight attitude.

The components are connected together with specific lengths of low
capacitance cable. The cable and connectors appear to be very similar
to that used in GM automobiles in the 1960s. At least my 1966 Pontiac
had a similar cable and connector from the antenna to the radio. It is a
hollow plastic tube with a very small center conductor that is loosely
coiled
inside the plastic tube. There is a braided shield over the outside of the
plastic
tube, and a outer jacket over that. Some people have pointed out it is very
similar to RG-62, 93 ohm coax without the spirial wound center insulator /
spacer. I measured about 10.5 pF per foot on a 28" piece of this cable with
connectors installed on each end.

This has been quite a project. I basically have seen all the components
work

in the airplane at various times, but the system as a whole is intermittent. Most time the wing leveler funciton works correctly but once in a while it wants to turn right. The pitch circuit has been working but is now acting up. The altitude hold was badly out of adjustment, but I was able to get that setup properly and working, but the climb and descent airspeeds are not right yet. I'm not sure if I've got bad connections, intermittent components
in the amplifier or both. I'm planning to pull the cable assemblies out along
with the amplifier and get it on the bench for testing.

Therefore, it would sure help to have a basic understadning of the amp circuit
during that process. Therefore, I thought learning about the transistors charateristics
and the inductance values would be helpful. I've already measured all the cap
values and ranges. Next step is to generate a schematic for the amp and learn how it is supposed to work.

It might also be fun to design and built a replacement for the amplifier using modern components.

Thanks again for your help.

Ronnie

Hi Ronnie,

As others have already pointed out to you, most of the numbers that you've posted are manufacturer's parts numbers, and not Motorola type numbers. (Unregisted Motorola devices type generally begin with the letter "M" except for some diodes.)

Checking in my 1966 Motorola Semiconductor Device Manual, the MA900 is a high-voltage switch that is usually employed for driving neon readouts, relays etc. The family is Germanium, PNP. The MA900 is not specifically listed, but two other later member's of the MA 900 family are. IIRC, the deviced listed in the book are the MA909 and MA910, which likely have improved parameters over the original MA900. Essentially a 75Volt devices with a current capacity of up to 200-Ma capable of 150-mw.

The 2N1192 is also listed (2N192-2N1194) as PNP germanium transistors for high-gain audio amplifier and switching use.

The book contains data sheets on both the above devices, which I would be happy to scan and email to you if you want them. Can't be of any help on the other devices.

Just let me know. My email address is hhc3141@yahoo.com, not the address shown on the post which is intentionally obsolete to discourage spammers.

73s, Harry C.

Ronnie, just as a suggestion, (although you've likely already tried), try and obtain a technical or service manual for the system. Many of these will included a cross-reference from the manufacturer's part ID to a and industry standard.

Even a Sams folder would help you here, if one was ever published. Nice thing about Sams folders is that they almost never go away once published, only become a bit brown with age! :-)

Thanks Harry.

I do have a service manual for the system published
by Piper, however it has no details of the electronic
compoents, only the electro-mechanical stuff. It does
have enough overall theory of operation information
to help get me started with the electronics. I'm also
trying to find out what help the orginal manufacture
can be. They are still in business, although operating
under a different name. So far, all I'm getting is their
hold message, but if I can ever get someone on the phone
I might get some help there.

Concerning your follow-up post, another gentleman has
already emailed me a scanned datasheet for the 2N1192
and the general info you provided on the MA900 like
devices should get me going there.

Thanks again for the help.
Ronnie

APRSPoint is the latest APRS implementation that integrates seamlessly with mappoint to allow you to track anyone on a street level detailed map. It handles imput from RF and internet feeds, and works with Kenwood radios with built-in TNC's in an easy to use interface. It is considered to be the most stable and intuitive, and ideal for first time users. We are offerring a special discount right now. Please visit http://www.aprspoint.com for details. Thanks.

It really helps to know how to throw yourself on the mercy of some marketing type to get to an Engineer who is willing to spill his guts or, give away the keys to the kingdom and send you a schematic and info. Done a lot of that over the many years as a Engineer-Ham...or is that Ham-Engineer.

Shouldn't be dreadfully hard, I think.

Assuming two frequencies F1 and F2, you'll get mixing products at
the sum (F1+F2) and difference (abs(F1-F2)). To deal with harmonics
and higher-order mixing products, I believe you can generalize this by
including two integer multiplier factors M and N whose values run from
1 up to as high as you care to go. Then, expect mixing products to be
at (M*F1)+(N*F2) and abs((M*F1)-(N*F2)). The amplitudes of the mixing
products will be lower as the multipliers go up... you could probably
kluge in an estimation formula of some sort.

Calculate the various mixing frequencies, and estimated levels in a
square matrix, link the data to a two-column arrangement, and generate
a plot of level vs. frequency.

Hi,
Stephan Ducharme here,

Here is how to attain freedom with your PC!

This short story will make you realize that you are so close to freedom if you have a PC (which is obviously the case). So let me show you how to reach freedom with it:

This morning, there was a Ladybug in the shower floor.

I looked at it and it made me realize that most people are in the same situation as that Ladybug.

She felt secure on the floor ... until I turned on the shower and water started to fall on the floor. Then she got scared and she flew on top of the shampoo bottle. But her wings could have carried her out of the bathroom window. She could have flown wherever she wanted. But like most people, we simply climb to the closest step.

So what happened to her right after really scared me.

When the water started to bounce off my head onto the shampoo bottle, she panicked and to my amazement, she flew back to the floor where she once found security!!!

Don't we do that?

So that is the reason why you haven't succeeded yet!

The bottle of shampoo simply was not the right destination.

Are you doing the good thing online to make any money? 95% of the websites you have seen don't make money. If you copy them, you won't succeed and first thing you'll know, you'll be back to your 8to5 job, frustrated!

You have seen lots of offers on how to make money with your PC, but for having bought a lot of programs myself and for being online for years, I know that very few teachers will show you the correct and complete way. There exist 9 simple steps and if I don't show you each one, then it may take you years to discover them on your own.

A man called me last week saying he has been online since 1998 and like a lot of people that have been online for many years, he still hasn't figured it out.

Once you have read my 9 steps, you will know where the window to your freedom is.

2351. Accurate voltage calibration

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-15 02:47:03 UTC
From: Alfred Green <nu8i@cox.net>
Message-ID: <K8Z%f.597$zf6.181@fed1read08>
Source record: 12552

I have recently aquired a nice 5.1/2 digit DVM, and would like to assess the absolute accuracy. Many years ago I had a 'Standard Cell', but that got lost in one of my several relocations.
What is a good alternative these days? I would think that there is a semiconductor device that has a known threshold. I am familiar with the Wheatstone bridge method to measure voltage without affecting the reference.
Once I have a good DC reference, getting AC & RMS calibration is fairly easy.
Having a GPS locked time and frequency reference, I am used to being at the 1e-10 accuracy level for those, but if I can get to 1e-5 for analog voltage I would be very happy.
Any suggestions gratefully received.

2352. Damaged resistor - what happens?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-15 03:29:04 UTC
From: KC2PIH@gmail.com
Message-ID: <1145071744.749424.325970@j33g2000cwa.googlegroups.com>
Source record: 12554

I have a carbon film resistor that got so hot that it melted itself free of the circuit board. Can the resistance (of the resistor) be permanently increased when this happens or does a resistor just become "open" when that happens? The reason I ask is because I have two resistors in parallel that go:

Black | Brown | Black | Gold

I think the resistance should measure ~1/2 Ohm, but my ohm meter reads 33 Ohms. Does this mean they are damage or did I do something wrong?

Thanks,
Scott, KC2PIH

Usually when I do that the color code becomes Black | Black | Black | Black.

Yes, if the resistance element burns off a bit without going completely
away the resistance can rise. In your case I suspect that you're
measuring other resistances in the circuit. Even if you're measuring
the actual resistance, 66 times the design value may as well be open.

You need to replace the resistors, and before you do that you need to
find and clear whatever fault it was that made them char.

Actually, I did a little more reading and the resistor is about .39" with a blue case. I think its actually a 1/2w metal-film, flameproof resistor (not a carbon film). Learning is fun!

The resistors being measured are unhooked completely from the circuit - so I know its not something else. Finally - I know what smoked these resistors already ;)

2355. MILLIONAIRE showers with LADYbug!

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-15 04:51:32 UTC
From: Stephan Ducharme <pulsar@weblifeisgreat.com>
Message-ID: <e1pn3g$v9$7@ctb-nnrp2.saix.net>
Source record: 12553

Dear Internet Marketer,
Stephan Ducharme here,

Here is how to attain freedom with your PC!

This short story will make you realize that you are so close to freedom if you have a PC (which is obviously the case). So let me show you how to reach freedom with it:

This morning, there was a Ladybug in the shower floor.

I looked at it and it made me realize that most people are in the same situation as that Ladybug.

She felt secure on the floor ... until I turned on the shower and water started to fall on the floor. Then she got scared and she flew on top of the shampoo bottle. But her wings could have carried her out of the bathroom window. She could have flown wherever she wanted. But like most people, we simply climb to the closest step.

So what happened to her right after really scared me.

When the water started to bounce off my head onto the shampoo bottle, she panicked and to my amazement, she flew back to the floor where she once found security!!!

Don&#65533;t we do that?

So that is the reason why you haven&#65533;t succeeded yet!

The bottle of shampoo simply was not the right destination.

Are you doing the good thing online to make any money? 95% of the websites you have seen don&#65533;t make money. If you copy them, you won&#65533;t succeed and first thing you&#65533;ll know, you&#65533;ll be back to your 8to5 job, frustrated!

You have seen lots of offers on how to make money with your PC, but for having bought a lot of programs myself and for being online for years, I know that very few teachers will show you the correct and complete way. There exist 9 simple steps and if I don&#65533;t show you each one, then it may take you years to discover them on your own.

A man called me last week saying he has been online since 1998 and like a lot of people that have been online for many years, he still hasn&#65533;t figured it out.

Once you have read my 9 steps, you will know where the window to your freedom is.

I don't think there is an easy to do what you want, otherwise people
wouldn't spend lots of money getting their standards calibrated at
national standards labs like NPL. Your best bet might be to find
someone who has access to a regularly calibrated DVM and check it
against that, or send it away to get it calibrated.

Standard voltage diodes are available and are used as secondary
standards, but are probably quite expensive and difficult to find.

You should have kept your Weston cell. 8-) BTW, NPL even offers a
calibration service for them, the volt is defined using a Josephson
junction, these days.

I'd suggest you either find a calibrator to connect your meter to, or make something you can use as a transfer standard. Maxim, for example, has some reasonably low cost voltage references with good stability (very few ppm/C). Then calibrate the transfer standard against some known in-calibration volt meter or calibrator, at a known temperature, and use it. I'd think in Scottsdale you could find a calibration service that would do the job for you, or maybe you know someone who has access to an accurate voltmeter. Of course, you should really do it for several ranges. You can maybe calibrate a voltage divider yourself, but it would save a lot of trouble if you could just do it directly. If you don't know anyone who works with more accurate instruements regularly and don't want to pay for a calibration, perhaps you could pay a visit to the EE or physics department in Tempe and use one of their instruments.

I've thought of making a secondary standard myself--I have several of the reference boards from HP3455 DMMs that have single specific things wrong with them, but combining them I have at least one good voltage reference, and one good DC 10:1 divider.

Don't EVER expect to get to voltage measurements with accuracy or even repeatability like you can with frequency--you would have to go to extreme measures to avoid thermal EMFs, for example, and even with some care they can give you part per million errors at low voltages. But surely it's rare that you'd need that sort of resolution, let alone accuracy, no?

Cheers,
Tom

If black, brown, black, gold was the original color code--well, it's a pretty strange code for a resistor, starting with black. But sub-10-ohm resistors should have a gold or silver third band, not black, so maybe it didn't change all that much.

My suspicion is that it _might_ be a flameproof resistor as you say, but it's quite likely that it's a metal-oxide resistor. The flameproof ones tend to act like fuses (to keep not only themselves but things around them from flaming!), but the metal-oxides have a long reputation of being able to not only melt the solder but burn a hole clear through the board before they give up as resistors. Most of the ones we use have a pale blue case that gets somewhat paler if they've run very hot for a while. I've done some experiments with them, dissipating up to ten watts in a two watt resistor for long periods, and noting that yes, they do change value some, but nothing like a metal or carbon film would. They will survive a long time (hours at least) at five watts with only a few percent value change. Yours could indeed have been orange-orange-black-gold before they got so hot that the paint changed color. I'm curious if you found a schematic or something else to tell you what the design value really was.

Cheers,
Tom

Ronnie,

I'm not trying to be an arse, but the "health and safety" part of me just
woke up...

What is the regs say about a homegrown repair of the autopilot or is it
classified as a non-essential unit or non-safety unit?

I assume the insurance companies would have a field day if you get a midair flat tyre or decide to make an accidental or sudden parking...

-- Which might be the initial reason for Mitchell to use selected components from Motorola...

I guess that the best way to get access to this info is to try to speak with the supplier. Even if they been taken over, the airplane industry tend to be paranoid on saving all data possible. Talk with the service engineers, if they are more than 5 of them, you have good odds for one of them being a ham!

Cheers

I can't get an original schematic. Yeah I guess the colors markings are ruined. There are bunches of this type of resistor in this circuit. They are all baby-blue, with very bright markings. This resistor was HOT. The blue is almost greyish now. Maybe I'll unsolder the two resistors and see if the values match exactly. If so, I guess that *might* be an indication that they are still good.

Yeah, the "bunches of" is another indication that they are metal-oxide parts. It would be pretty unusual to have bunches of flameproof parts in a circuit, I think. The metal-oxides are good parts, but you do have to be aware that they can survive being really hot better than a lot of things around them can.

Cheers,
Tom

Not sure if it is relevant to modern materials, but when I worked for the National Research Council (Canada) many years ago, I used to make dummy loads by mixing a powdered ferrite material with the then-available epoxy cement and pouring a tapered slab of this mix into the waveguide. (These were used as the flat load at liquid nitrogen temperatures in a Dicke radiometer at S and X bands.)

Steve,

I assume you don't intend to run to much power thru' your bridge.

One of the best and "homebrew friendly" ways is to wind a ferrite based
directional coupler. I assume you intend to work with the usual 50 Ohms...

I used a small rf ferrite trafo from Coilcraft. It's a SMD sized two hole
ferrite and by ripping out the original transformer wire and replacing it
with the wiring of a DC, I got a nice DC for up to 1000 MHz.

The range of toroidal couplers can span two decades of frequency and 2MHz to 1200 MHz is not impossible.

I normally wind the DC with a 1:3 to 1:5 N1/N2 ratio. That gives me about 0.5 dB insertion loss and about 10 dB of coupled port loss.

As long as the copper wire only touches the ferrite on the corners (as little as possible) the linearity is surprisingly good and I can expect a return loss of 25 to 35 dB - wich is enough for most aerial measurements. I'm using these DC's for measurements between 1 and 500 MHz with good accuracy.

I suggest you look for :

RF Directional Couplers by Michael G. Ellis, Ph.D.

Cheers

Dan / M0DFI

Background:
Tired of listening to Led Zepplin or NPR on your I-Pod? Wouldn't you like to be able to carry with you the kinds of ham radio conversations that you listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in London, England meet regularly on the ECHOLINK system to discuss their homebrew radio projects. We are making them available as PODCASTS.

You can subscribe to the program, have them downloaded to your MP-3 player, and listen to them at your convenience. To subscribe, just cut and paste this URL into your I-poder (or similar) software. (There have been some problems with this subscription URL.)

http://www.ourmedia.org/mediarss/user/36170

If you don't have an MP3 player you can just go to the site below and listen to the latest program (and earlier editions) using the audio software on your computer.

http://www.ourmedia.org/node/206607

Here's the homepage for our show. All our programs are available here. There is also a blog and links

to some of the sites and documents we've been discussing: http://www.ourmedia.org/user/36170

We hope you enjoy the program. Please send us feedback.

73 from London

....yes, you can, provided you use Araldite slow setting epoxy (the
blue kind).
don't forget that the FR4 board is made of it!
while working at Tadiran, years ago, we found out that the slower the
epoxy cure the better its RF characteristics.
we never found out why- actually we never tried hard enough- but the
fact remains.
on higher frequencies you have to be careful, but Bluetooth thrives on
FR4 (at 2.4GHz)!.

Most everyone has a screwdriver or two laying around the house, but not everyone has a minimum collection stored in a tool box. If you know a young person graduating from high school, a single relative, or even yourself, a tool box with a minimum complement of tools may be the perfect gift.

Based on my own experience, the BASIC TOOL BOX should include:

A plastic or metal box such as the 13" plastic box from Walmart or the 14" plastic box from Lowes. The box should have a secure latch that won't come open when picked up.

#1 Philips screwdriver

#2 Philips screwdriver

1/8" Flat blade screwdriver

1/4" Flat blade screwdriver

Standard pair of slip-joint pliers with insulated handle

Diagonal cutters with insulated handle

Long nose pliers with side cutter and insulated handle

Small claw hammer such as Sears 3805 - 7 oz.

Depending on your knowledge of the individual's needs and the size of the box, additional items might include:

Full-size hammer

Crowbar or pry-lever

Flashlight

Tire pressure gauge(s)

Pocket knife & sharpening stone

Soldering iron & solder & soldering braid

Digital multimeter

Set of nut drivers

Set of Allen wrenches

Set of Torx drivers

You get the idea!

What about Posidrive screwdrivers ? These are similar to Philips type of
screwdrivers but have additional 'notches' (if that is the correct word)
for better grip . The relevant screw heads are accordingly.

Frank , GM0CSZ / KN6WH

PS Most screws used in the UK are now of the Posidrive type.

Well, maybe askimg for 1e-5 was very optimistic, but I would like to see
what can be done in a home environment.
For ham use I couldn't justify getting it professionally calibrated, but
I'll check with the test-equipment guy at work to see if we have
something recently done that I can do a comparison from.

> Standard voltage diodes are available and are used as secondary
> standards, but are probably quite expensive and difficult to find.

That was kind of what I was looking for. I really am prepared to pay a
few bob for something that I can reliably use as a reference in my lab.

> You should have kept your Weston cell. 8-) BTW, NPL even offers a
> calibration service for them, the volt is defined using a Josephson

>

Oh yep. I think it was amongst the stuff that got lost in the move from
UK to the States back in '85. They do show up on Ebay occaisionally, but
I'd like to think there was something newer that could do the job.
Interesting to hear about the current Volt definition: I'll do some
searching for some more info on that.

Thanks for your comments,

Yes, that's pretty much what I'm looking for. The only problem with
Maxim is that they have SO MUCH good stuff it makes it hard for me to
find what I'm looking for. I'll try a more directed search.

> Then calibrate the transfer standard against some
> known in-calibration volt meter or calibrator, at a known temperature,

Yes, I can do that. I already have a temperature controlled environment
for my frequency sources.

All good points. I have friends at ASU that could help with this, but at
the end of the day it still has to come home with me. Back to the
transfer standard issue.

> I've thought of making a secondary standard myself--I have several of
> the reference boards from HP3455 DMMs that have single specific things

Hmm. The unit in question is a HP3478A. It has a 'CAL' button, but I
haven't hunted for a manual yet so I dont know what it does. Any ideas?

> Don't EVER expect to get to voltage measurements with accuracy or even
> repeatability like you can with frequency

Oh no, I wasn't expecting that. Even my comment about 1e-5 was really
tongue-in-cheek. However, I really can't point to anything in my shack
that can even approach 1e-2 in any repeatable way as far as voltage or

current measurement goes. I just feel that in this day and age I should be able to do better that that.

Frank-

I've heard of Posidrive. I think they are used in an old Hewlett Packard
counter I have. However, the tool dealers I asked had never heard of
them. I ended up using a common Phillips driver for my counter.

Certainly Posidrive would be a better choice where they are more commonly used.

I'd consider looking for some other tool dealers to do business with. Pozidriv (a registered trademark of Phillips Screw Co.) screws and drivers are very common, sold by just about every tool company from Snap-on through Stanley to Sears.

Tektronix used Pozidriv screws exclusively for many years, until they converted over to Torx. A standard Phillips bit fits poorly in a Pozidriv screw, making it really easy to chew up the screw with this combination. Any decent toolbox should include some Pozidriv drivers or bits.

2386. Buildig block IF amplifiers?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-18 05:25:17 UTC
From: clifto <clifto@gmail.com>
Message-ID: <tq9eh3-841.ln1@remote.clifto.com>
Source record: 12587

Has anyone played with any of the new high-bandwidth op amps in IF amplifier circuits? I've got an idea I want to experiment with, and not a whole lot of analog design ability (though I do better with building blocks than with compensating discretes), and now that GBw products are cheap above 1 MHz it might look practical to pursue. I have no standards for comparison since I know nothing about parameters like noise figures and the like in standard discrete circuits.

2387. Fading signals

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-18 05:40:39 UTC
From: clifto <clifto@gmail.com>
Message-ID: <nnaeh3-r41.ln1@remote.clifto.com>
Source record: 12588

Has anyone gotten a good oscilloscope look at the type of signals
that distort by cancellation of part of the carrier, i.e. the
signals that synchronous detectors detect much better than other
types? I'm wondering about the characteristics that make these
signals so hard to understand when they "fade" into that condition.

2388. Finding short duration interference?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-18 10:40:12 UTC
From: mike <spamme0@netscape.net>
Message-ID: <1249ghuscr3fneb@corp.supernews.com>
Source record: 12589

What's a good method for finding short duration interference?

My 440 repeater is plagued by an interfering signal that lasts a small
fraction of a second, just long enough to bring up the repeater,
and repeats randomly every 20 seconds or so.
Comes and goes...Seems to be dependent on outside temperature.
Sometimes sounds like there's hum on the signal.
First thought was that it was one of those oscillating Winegard
RV TV antennas, but it doesn't seem to drift around like they
typically do.

I hooked the repeater antenna up to the spectrum analyzer,
but the duration is too short to get thru the filters at
the bandwidth required to get any sensitivity.

I can hear it on the mobile.
I've driven around the neighborhood, but the duration is so short
that I've not been able to track it down. Strength seems to peak
at different places blocks apart...but it's hard to tell.

I have some experience with a double duckey and started designing
a doppler system, but it occurs that the short duration signal
will be completely washed out by the Switched Cap Filter. Don't see
how I'm gonna get the low rep-rate signal past the noise. Filter
types that I know about ain't gonna work.

Ideas?
Thanks, mike

Don't forget a 4" pipe wrench for those tight spots! It has been a
real life saver to remove broken studs and broken pieces of bolts. I
have one made by Rigid.

BTW, you won't bust your knuckles if you buy a real wrench. 8" is too
short to get a good grip on things. I have a 12" and a 14" "New Britain"
adjustable, along with a 4" Xcelite in my electronics tools.

The only tools I usually have to buy these days are new ones to
replace what walks away. :(

GBw products above 1MHz have been around for a long time in op amps, if you don't mind dropping the bucks then you can even get GHz numbers. There's very little stopping anyone from using even the old high-bandwidth op amps in IF's. But there's not much need to.

In IF strips for FM receivers, most op-amps do really bad things when they hit their limiting amplitudes. Google for "phase reversal" with "op amp".

"Straight" op-amps are not easily amenable to AGC action, but I've done some playing around with for example LED/CdS optocouplers as very linear controllable-loss blocks for AGC action and they work fine up through the low MHz. Above a few MHz I think capacitance across the CdS photocell gives too much leakage in typical receiver use, although if you only want a limited amount of AGC I think you're good to go.

It is MOST interesting to use chips like AD603's in IF's if you want AGC action. Many many app notes and construction articles on the web will show you examples of use.

Are you perhaps really talking about RC active filters to replace crystal or mechanical IF filters? I have always been VERY PESSIMISTIC about this, usually even few percent tolerance capacitors (not cheap) cause your passband/ultimate rejection to be way way worse than what you expect. Different filter topologies have different tradeoffs, but RC active filters when you want the Q to be >100 and want even mediocre ultimate rejection are economically unfeasible in every analysis I've done.

Tim.

A common problem is to turn the adjustable wrench around the *wrong
way*! I've had people argue that there is no wrong orientation for the
common 'C' (Crescent) wrench, but there most certainly is. Do it wrong
and you'll be fine 75% of the time; but that one time when you need it
to really bite--and you do it wrong--*you* are the one who gets bitten.

How well does it work the other way around -- using Pozidriv screwdrivers on
"regular old" Phillips-head screws?

I'm not as pessimistic as you, but I share your disappointment to some extent.
However, if a filter doesn't need to be in "active duty" 100% of the time,
having it self-calibrate seems potentially viable, at least for lower order
filters.

I'm usually after active filters for the sake of space, and consider Q>100
difficult to achieve at HF with any physically small design.

I do enjoy the occasional posts from people whose SPICE simulations show
ultimate rejections in the couple hundred dB ballpark. :-)

If you are talking about AM reception (and I think you are): I highly recommend that you have some fun with an ISB (independent sideband) receiver, with USB and LSB going into different ears. It's fun. Not sure exactly what you learn :-).

I would also recommend that you look at spectra +/- a few kHz rather than just waveforms. You can clearly see selective fading rolling up and down under some conditions and hear the resulting distortions.

I too am generally interested in homebrew synchronous AM detectors. I am not convinced that they are better than diversity antennas or ISB listening (of course not everybody has diversity antennas or ISB receivers.)

Tim.

Yes, most people seem to use it backwards where the stress is against
the front of the movable jaw, rather than the back where its supposed to
be. It doesn't matter if the item is fairly loose, but when you really
need the torque, it needs to be turned the right way. Maybe they need
to cast notches for your fingers to show people the right way to use it!

I'm trying to but my shop back together. I haven't really worked in
the shop since the middle of 2001, right before I got sick and lost my
job. Now, its been five years and two years of hurricanes that made the
mess even worse. Some squirrels nested in the building and chewed the
cords off of everything in sight. I had to put rat poison in there to
kill them all. I'm missing two cordless drills, two surface grinders

and enough hand tools to fill a couple large toolboxes. Since I no longer do any work away from home I have started hanging what is left on pegboard over the different workbenches.

The engineers at my last job liked the Mini Circuits ERA and similar monolithic amps. They also liked to do most of the AGC on the front end rather than at the IF. This sometimes included an electronic attenuator to drop the gain by 20 dB to prevent overloading a critical stage. The customers liked the way they worked, they ordered plenty of them at $20,000 USD each.

Hirose make lots of small shielded connectors that should be fine for 1MHz. They aren't cheap. Unless you are operating in a particularly noisy environment, though, I wonder why you couldn't just use a three or four pin header (ground on just one side or in the middle, or symmetrical ground on each side). Will you be connecting and disconnecting them often, or is it more a set-and-forget application?

Have you done any phase noise testing on the LMS485? I'm wondering how well they work for precision clock distribution. It's an interesting idea. We find that ECL keeps close-in phase noise quite low, and could drive the usual 100-ohm-differential RS485 bus, at least singly-terminated.

Cheers,
Tom

********** REPLY SEPARATOR **********

The flutes on a Phillips bit are tapered; on a Pozidrive they are
parallel. In many cases you can use either bit on the other, but if
available, use the correct one.

A Phillips bit can "lever" itself out due to the taper, where a
Pozidrive will not.

Not sure just what you mean, but AM needs a carrier to work. In an envelope detector, the carrier is needed to have the correct waveform so that the audio can be extracted. If there is no carrier, or too little, the waveform is not what is needed for the detector to work. Listen on a sideband receiver and you don't need the carrier and only the fade occurs with no distortion.
Just look at the waveforms for AM and Single sideband in tutorials which are all over the web and it is obvious. If the carrier goes down, you don't get that waveform. I couldn't find any good papers on the web showing the waveforms of AM and what happens as you reduce the carrier, but,...
Here are some references that may help you.
http://www.st-andrews.ac.uk/~www_pa/Scots_Guide/RadCom/part9/page2.html
http://www.radio-electronics.com/info/receivers/synchdet/sync_det.php
http://www.radio-electronics.com/info/receivers/am_demod/diode_am_demod.php
Compare the waveforms in those with what is here.
See Fig 1 in this paper. http://www.scott-inc.com/ham/ssb_im.pdf It is what you see when the carrier fades compared to the classical waveform you see for AM above. Note the nice sine wave is gone.

In my experience, it works better than using a Phillips driver on a
Pozidriv screw. But it still doesn't fit really well.

Hi,
Using a 90mm form with the centre as 50mm in diameter (like the ones in my previous photos) 2mm thickness with #22 wire you'll have 18 turns, 8-3/4 turns and 4 turns respectively.
I wound my tickler on the outside...that makes it easier to adjust.
Depends on your circuit but I'd guess maybe 4, 2 and 1 would be in the ballpark.
Let us know how it turns out.

Thaler has the best voltage references -- there was a design in one of the rags (Nuts n Volts or QEX) a few years ago in which 3 Thaler references were placed in parallel for a super reference. Email me privately if you would like a copy.

Also, get a copy of Linear Technology Application Note 86 "A Standards Lab Grade 20 bit DAC with 0.1ppm/degC Drift" -- Jim Williams is the author -- and make sure to read the appendices. Williams also did an ApNote with a comprehensive history of voltage measurement techniques, but I forget the application number.

You need a professional direction finding gear, probably from the DoD marketplace.

You can by all means build gear to trace this kind of interference but be adviced! the Guru factor is very high!

If you set up an array of 3 or 4 antennas, you can compare the phase difference from the different antennas and by that triangulate the position. You need to have a fast trigger mechanism and memory to be able to make a constant monitoring with a monitoring stop triggered by your signal. As a receiver, you should probably use a sdr rig or a wide >1 Msp ADC to catch spur's on 440.

In other words... It have to be very annoying before one starts of this expensive hunting of spurs!

A nice project for homebrewing tho'

Cheers

OK Guys! I've done some more checking, and still can't find a store that sells Posidrive or Pozidrive. I have one lead to a specialty tool store across the state, but the local Ace, Sears and Lowes don't carry either the screws or the drivers.

I can see where the Posidrive may be used in some electronic equipment, but all of the screws in the hinges in my house, as well as the screws holding the locks on the doors, are definitely Phillips. Are Posidrive screws used for those applications in other countries?

I can see now that my original list should have stopped without the additional items. The purpose was to define a really BASIC set of tools for use around the home!

Thanks for the suggestion. I must admit to never having heard of of
'Thaler', but a quick search has thrown up some really interesting
stuff. No online ordering, but an 800 number to find the distributors.
I'll follow up on that.

I'll get the LT AppNote. Thanks for the info.

can you just duck the problem and use a PL tone Iknwo when we lived in
sprinfeild it worked welll a 2 m repeater and another 440repeater in
the general area that worked out well too

The real advantage of Pozidriv is in applications where something is
mass produced with the screws put in by power drivers, so they're fairly
common in manufactured goods. I was really directing my earlier comment
that every toolbox should have some Posidriv bits or drivers to people
doing any kind of work on electronic equipment or other kinds of
manufactured goods. Posidriv tools probably wouldn't be of much use for
most household repairs, so wouldn't be appropriate for a very basic
household tool box. The same goes for Torx.

You can identify Pozidriv screws by a ding in between the slots. There's
a good picture at http://www.aaronsscrewdrivers.com/PowerBits.htm.

I haven't seen complete Pozidrive drivers anywhere around here, but
Orchard Supply (local hardware outlet) has Pozidrive bits in several
sizes, which will go into the usual magnetic-hex-socket driver
handles. In fact, just yesterday I glanced over their $2.99 "17 bits
in a small carrying case" assortment by the cash register, and found
that it contains 3 Phillips and 3 similarly-sized Pozidrive bits.

Hi Alf,

I'm not familiar with that particular model (HP3478A). We used to have a complete set of microfiche for all the HP product line, back to the HP200 oscillators, but unfortunately someone else coveted it and we don't have it any longer. Sorry I can't be more specific help. You should be able to find a manual somewhere--there are places that specialize in used manuals. Or you may find it online--if not now, it may show up before too long (I just don't know how accessible it will be...)

Cheers,
Tom

I've kept a long, slim, scalpel (+ pack of spare blades) in my toolbox for over 40yrs, wouldn't be without them. Can be used for cutting, poking, as an improvised instrument probe and (if push comes to shove) the final solution to that b****r of a problem ..... provided you fit a new blade first !!

==========
Most wood screws in (at least)western Europe are now posidrive ,because
the grip is so much better ,which is necessary due to the frequent use
of electric screwdrivers.

A tool company Draper are selling chromium-vanadium steel screwdrivers
in sets with coloured plastic grips (in the UK)
A set comprises 3x3 ,total of 9 screwdrivers
Flat blade : Red grip
Phillips : Blue grip (or is it Philips?)
Posidrive : Green grip

Talking tools , I consider different dental 'poking'utensils and
twizzers essential for dealing with circuit boards ,especially in the
homebrewing arena. I use these frequently.

You can buy an Exacto knife a lot easier, and there are a lot of
different blades available.

Hi Alf,

Look at this item on ebay. This guy makes little reference boards for
a good price. I have had conversations with him and got some good info
on standards.

http://cgi.ebay.com/10V-L-STANDARD-VOLTAGE-REFERENCE-NIST-TRCBL-CALIBRATOR_W0QQitemZ761044
1828QQcategoryZ25399QQssPageNameZWDVWQQrdZ1QQcmdZViewItem

If the link doesn't work search ebay on "voltage reference".

I built a little standard using a different chip than he used. I used
an LT1019A and trimed it in.

I have a small spread sheet comparing his board with mine and the 731B
transfer standard if you would like me to send it to you.

He had sent me one of his boards to play with. I found that they move
quite a bit with temperature. Temperature is the biggest problem in
maintaining a stable reference with those chips. I have a fluke 731B
transfer standard to reference to, using an hp 3456 voltmeter to
measure things with.

The board he has is not a bad deal as he sends it out calibrated. If
you can duplicate his temperature you will do pretty good but probably
not quite as good as he advertises.

A good pre regulated supply is important to feed the reference chip
too.

Thanks for the reference to the references, Jack. I emailed them, and
got back a nice reply that said, in summary:
-- Yes, they sell singles, no problem.
-- Order direct from them.
-- Current prices for four items I asked about are
** VRE100C $43.50 4 week lead time
** VRE102C $48.73 in stock
** VRE302AS/AD $11.04 in stock
** VRE302CS/CD $6.52 in stock

Those first ones are extremely low tempco parts (typ. 0.3ppm/C) with
very good initial accuracy (0.01% max error), +10V and +/-10V. The
second two are 2V parts with still very good tempco and good initial
accuracy. See their website for details.

Cheers,
Tom

I think this one best illustrated what I've read sparse information
about, that multipath will sometimes cancel part or all of the
carrier.

We built tubular filters in house, because we couldn't get what we needed, when we needed it. We built the ground station and a mobile earth station with a large mobile diesel generator for power, for the Italian government to track their launches. They had a severe overload problem, trying to set up the one station near the launch pad. Engineering was going round and round about a way to reduce the signal levels prior to the launch, that could be done quickly. My suggestion was a chain link fence near the pad to block most of the signal, till the rocket left the pad and was no longer pointing right at the ground based antennas. The receivers had lots of aluminum between stages to stop stray signals.

We used a LINEAR AGC system that was a pain to get set up, but the dual diversity combiner required the linear 0 to 5 volt signals to steer the combiner.

One good thing about the Thaler references is that they provide a
Temperature Output -- so if you are using a Fluke, Keithley, HP-Agilent DVM
with GPIB, HP-IL or RSwhatever you can compensate for temperature
differentials.

Of course, you can also use the temperature output to drive a differential
amplifier and "cook" the unit to a constant temperature much as we used to
with crystal oscillators (boy, am I dating myself now :)

Clifto,

Is your goal a project to get hobbyists with AF project background into RF building with a minimum of giant steps (or something like that)? If so, the familiarity of op-amp building is probably a good choice. Introducing ceramic filters and the need for a ground plane can be enough for hobbyists doubtful about entering a higher frequency range. Getting something to work will build confidence. You can make more satisfying results a later step.

The LT1019A Linear Technology chip that I played with has the same pin
to give a changing output as the junction temperature changes. However
LT says that it is pretty much useless for actual temperature
relationships. I took measurements with that pin and also found it to
not correlate with temperature close enough to do anything with other
than give an indication of change. I believe it is buried to far into
the junction.

Actually, I want to play a bit myself, and my analog design "skills"
(if that word applies) have always been weak. I've always been a
much better troubleshooter than designer.

Oscillator construction seems a big problem up there. Was trying something similar the other week. Turned out 99% art 1% science, so packed it in and now awaiting a sample of an interesting satelite downconverter chip. http://www.semiconductors.philips.com/pip/TDA8261.html , digitally covers 950 to 2175MHz using a VCO/synthesiser running at a quarter of it's mixer input frequency. VCO simply consists of a Varicap, 2 caps and a 18nH inductor. Chip is 'direct conversion'(with quadrature outputs!) and would make a wonderful 0-1GHz spectrum analyser if it's mixer ran down to a few megs. Sadly, no mention of this spec' in the datasheet, so must assume response tails off badly at the low end.

Hi gang,

And old chum of mine suffers badly from pager interference when he's trying to listen on the 2m band. The interference is strong to him (S9+) and takes out all his reception, despite the fact that it's quite a way up-band at 153Mhz.
I've been looking into designing a filter for him to cut off by 153Mhz to better than -20db but it turns out to be rather more tricky than I'd imagined. Even with a seven element butterworth configuration, the difference between the 146Mhz (wanted) and the 153Mhz (unwanted is an insignificant 6db or so. I'm just not getting enough roll-off and need something much sharper. Worse still, the roll-off I'm seeing is on a computer simulation of the filter with ideal components and would no doubt be even worse with real-world Ls and Cs. Any suggestions as to how to tackle the problem, guys?
Thanks,
P.

A coax stub filter to notch out the pager would probably work better. It's cheap to make, but it also has some drawbacks - signals within roughly +/- 10 MHz of the notch may have as much as 10 dB of attenuation. Your friend may be able to cope with some attenuation better than 100% overload.

The previous poster is correct- a notch- particularly an asymmetrcial notch
is the proper solution.

50dB or greater attenuation at 163 MHz with in band loss of under -0.4dB is
easily achieved. See:
http://www.eham.net/reviews/detail/3716

PAR Electronics makes some two- and three-section anti-pager notch
filters which are quite effective. From their looks and construction
I infer that they use helical resonators. Might be possible to
homebrew something similar?

A notch filter is the easiest thing to do. While a pass cavity will
probably work too it will be quite large and expensive.

Try a small box with connectors on either end and a wire passing
through. connect a series tuned coil / capacitor resonant at the
offending frequency. You can get up to 30 db of rejection with a
single notch. Two circuits connected side by side will improve around
another 10 db. A quarter wave length cable (and shielding) between the
two circuits will approach 60 db if needed.

The higher the Q of the circuit the narrower the notch will be and the
less loss of the wanted frequencies being passed through.

Design a network that has a notch at 153 AND passes 146. Just the notch is not good; it will have significant attenuation at 146. In terms of poles and zeros, you want a transmission zero at 153 and a transmission pole at 146.

One way to do this is with a coaxial resonator. The separation is great enough that it shouldn't take a super-high-Q one. You tap your input and output a short distance up from the shorted end of a quarter-wave stub that's open on the other end. The distance from the open to the attachment point is 1/4 wave at 153MHz, which reflects back a short to the line at 153. But that's capacitive at 146, and resonates with the short stub between the attachment point and the shorted end to yield a high impedance across the line there.. You can do the same thing with a couple coils and a trimmer cap: something like 10nH across the line and a series-tuned tank of 100nH and about 10.8pF right at the same place would do it. Coil Q should be pretty high to have a deep null and avoid loss at 146. You get to figure out which will give you better performance.

Cheers,
Tom

Actually 6 dB may be of some help, since the problem is probably caused by 3rd order intermodulation between two signals and the attenuation of the intermodulation product will be greater. However, as the others have pointed out a low-pass filter is not likely a good solution. Either the notch filter suggested or a bandpass filter should be better. There are some 2m bandpass filter designs in the RSGB VHF/UHF Handbook 3rd edition, if you can borrow a copy.

I'd try that first. I work in cable tv and one of our older methods of "scrambling" was to use an interfering carrier ~2 MHz above the video. It was fairly easy to use a little stub of coax and completely remove the jamming...ie >40db of rejection with only a few db hit on the video carrier 2 MHz away. In your case 7 MHz away it (insertion loss) will be a non-issue.
You'll find the stub length to be critical to about 5mm so its a true cut-n-try technique. Use some old scrap television cable for the stub so you don't waste the good stuff.

Source record: 12448

I question the bit about insertion loss 7MHz away being a non-issue with only a single open stub across the line. If you put an open stub of lossless 50 ohm line a quarter-wave long at 153MHz across the feed line, it puts a short across the line at 153, but it puts 0.26-j3.58 ohms across it at 146MHz. That's a 99% reflection, or SWR close to 200:1 at 146. It's only about a 17dB loss, but that's more loss than I'd want.

But if you also put at the same point across the line either a shorted stub or an inductor to resonate that, it will let 146 pass much more easily...the inductance required is only about 4nH, though, so it ends up being a pretty short piece of wire, and a Q of 20 results in almost 3dB loss. Still, that's a lot better than 17dB loss.

Also, you can tune a stub by making it very slightly shorter than calculated and adding capacitance to the open end--an air-dielectric 50 ohm stub cut 1cm short, with a 1pF capacitance across the open end, tunes back to 153MHz. A little piston cap lets you tune it right on the offending signal. (You can also make the 146MHz peak tuneable by using a stub a bit _longer_ than 1/4 wave at 146 in place of the inductor, and putting a tuning cap on it too...then it's easy to tweak right in for optimum performance.)

These what-if scenarios are easy to simulate in RFSim99, which is freeware. There are lots of variations on the theme, but at very least, it's a quick check of a proposed solution to see if it's really all that good at both getting rid of the offender and passing the desired signal. Be sure to include expected loss resistance to simulate the finite Q of real components.

Cheers,
Tom

Anyone have a favorite low power (as in tens of milliwatts) receiver IC that you can still get ahold of? I'm looking to see what could potentially replace some Philips UAA2080's, which are no longer available new from Philips. They were a really great part, giving you an oscillator, frequency mulitplier, RF pre-amp, I/Q mixers and a bit of demodulation (they were intended for use in pagers but gave you the raw I/Q output so could be pushed into service for other applications too) -- all of this for less than 10mW!

Looking around at parts, it seems that even plain old mixers now often run 50mW or more. Ostensibly this seems due to their usage at higher frequencies (low GHz range), which I can understand, but it's a feature don't require. I'm after low power parts for dealing with more pedestrian frequencies (low to mid-hundreds of MHz) and small bandwidths (single digit kHz).

Thanks,
---Joel KOlstad

Hey, if you find one let me know!

Have you considered looking at one of the obsolete-components suppliers?
It sounds stupid, but it seems like a lot of good RF parts for VHF are
going by the wayside as everyone gets on the GHz bandwagon.

Maybe we could hire Jim Thompson and start a company...

I get no posts in rec radio amateur antenna. Is anyone else having problems?
I had some problems the past couple days, but today nothing appears.
Mike

Most manufacturers seem to be obsessed with "high intercept point", which is desirable in some instances, but always carries a major power penalty.
With the demise of some of my favourite ICs, I'm going back to discrete components for many things.

Bob

The "alive" part Roy mentioned I agree with. I'm not so sure about the "well" part, but that's just my bias I guess.

You can always use Google to check activity on a group. Well, not ALL groups, but lots of them. To post through Google, you need to log in, but you can read groups without doing that.

Cheers,
Tom

What do you mean by simple receivers ? What are you trying to receive, with what stability and sensitivity ? Amateurs have traditionally used crystal-controlled downconverters in front of lower frequency receivers, but this is generally suited only for receiving small segments of spectrum and doesn't usually have a very small parts count. The local oscillator usually involves several multiplier stages and tunable filters. The performance can be very good though.

For example there are lots of technical articles at

http://dpmc.unige.ch/dubus/index.html

The 1N5711 schottky diode works well in the lower microwave range and is quite widely available and cheap.

Hi All,
The article below shows a low distortion antenna amp for BCB and SW.

http://www.kongsfjord.no/dl/Amplifiers/Ultralinear%202N5109%20And%202N3053%20Amplifiers.pdf

Note the wrap.

When built as a push pull it has stated specs such as
12db power gain
ICP2in +100
ICP3in +35
Flat from 100khz to 30 Mhz
I'm interested in comments, and I'm also trying to generate some interest
in maybe some simulations to work on biasing options.
The author states more work needs to be done on transformer winding
ratios.
Take a look, it is an interesting article.
Mike

Beanie's got a boyfriend, Beanie's got a boyfriend.....Seriously Morey a few people do agree to a degree with Beanie but it's the pathetic repetitive way he goes about it that drives everyone nuts... If he was to make a less insulting post with the same basic points then I feel he would get much further in his quest for all things "Hammery"...

Yes, it's an interesting article. I do think you need to ask yourself exactly what problem you're trying to solve before just jumping in, though. One thing that can be very useful is an antenna/preselector that can get rid of "boomers" before they get to the amplifier. For example, a small tuned loop can be oriented to null an on-frequency interfering signal, and will have enough selectivity (assuming it's tuned) that off-frequency boomers will be much less problem. That doesn't work if you _must_ listen to everything all the time, though even then notching out one or two large signals can be useful. Because of the very high atmospheric noise on MW and even up into HF, there is seldom a need for a very good noise figure; the distortion performance takes precidence because of all the large signals around.

With a good antenna, there may be no need for an amplifier before the mixer at all, and it's possible to build mixers with input IP3s up around +50dBm -- there are people that read this group that know how to do that. Once past the mixer, you can filter, and if your _filter_ had low enough distortion and selects the signal you want while attenuating others, the rest of the amplifier chain doesn't have to be _quite_ as good.

I have an abiding interest in amplifiers with good distortion performance over just the band mentioned, though, and I can tell you that over most of it, you can do quite well with modern op amps. One example (but not the only one) is the circuit on the front page of the OPA847 data sheet. The OPA847 also has very respectably low noise. There are a few non-operational-amplifiers that do quite well, too. The IC amps generally have more noise, I think, than what's mentioned in the article (I haven't read it all -- yet), but they should be adequate for at least MF and lower HF work.

Just this morning I came across a PDF talking about using simulation software to optimize an amplifier for good distortion performance--it was an ap note that touted the (somewhat expensive for ham use) simulation software from that company. I didn't bother downloading it because it was out of both my price range (the software) and my frequency range (the ap note).

I'm curious about comments from BCB DXers--from what I've seen, it's hard to find signals you could listen to that are all that small, because there are so many stations on the air that every "channel" has something at least moderately large in it. For example, I see local stations here at about -30dBm on the antenna I'm using, and I can see signals every 10kHz across the whole band that are seldom lower than

-100dBm--just one or two that are lower than that and not by much. In that situation, a +40dBm TOI should be adequate: distortion from the -30dBm signals would be 140dB below them, or 50dB below the smallest signals I might want to listen to. But maybe if I spent more time looking at other times of the day, I'd get different results...and certainly having a neighbor running a kW on the same HF band I'm trying to listen to would require much better performance.

Cheers,
Tom

The application where I saw this used, was in an antenna phasing unit,
the low distortion helped reduced mixing products in the output of the
phasing unit. I didn't see any noise figure in the article, but was told it
was 3 or 4 db, (ten years ago).

I'm thinking of using the amp on a Flag/Pennant antenna
which has a low output.

I don't have the understanding of the numbers you seem to, but I heard
others look for better amps because of mixing products especially on
the AM band.
The trick in the AM BCB is to null out those large signals to hear
the smaller signals.

2467. Homebrew connectors

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-23 01:07:29 UTC
From: Bob Liesenfeld <wb0poq@visi.com>
Message-ID: <444AD351.AD9EA178@visi.com>
Source record: 12468

Hi gang,
I've been thinking about making some homebrew connectors for RG-174/U coax. I plan to use them to interconnect several enclosures made of PC board material. I envision something like an SMB connector made from some of the brass tubing that can be found in hobby shops. Rather than re-invent the wheel, I thought I would ask here if anyone has done something like this. The goal is to avoid the large size of something like a BNC connector along with the attendant high cost of most all RF connectors.

Tnx!

Bob WB0POQ

Why not use SMA or SMB? I used perhaps 30- 40 in my homebrew RX and it makes for easy fast connect/disconnect. The connectors are cheap as are the crimp tool. One can assemble a jumper in 3-4 minutes. I would not advise the RG-174 if you will be doing any soldering. Spend a few pennies more per foot and use RG-188/RG-316 teflon.

Where do you get connectors? The ones I see in Digi-Key are something
like $5.00 a crack. If I'm missing something please let me know!

Most of the equipment I've seen at University EE departments (even
grad school), hasn't seen a calibration lab in 3 or 4 decades.

Some time back, a firend gave me a Leeds & Northrup Presision
Potentiometer. I've used it occasionally to check some voltmeters,
but I don't have anything over 3-1/2 digits of resolution.

2472. Best way to build fixed 1.6GHz locked oscillator?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-23 05:04:53 UTC
From: 3flp <zalio@optusnet.com.au>
Message-ID: <1145768693.594483.54000@e56g2000cwe.googlegroups.com>
Source record: 12473

Hi,

I'm in the process of designing a simple scalar network analyser. The synthesizer will use 2 PLLs. One tuning from 1.6 to 2.6GHz and the second on locked to 1.6GHz. I hope to create a DC to 1GHz output. I'll use Minicircuits or similar for the broadband VCO. But it seems a little wastefull to use the same thing for the fixed frequency PLL. So here's the question, what would you experienced home brew gurus recommend?

The oscillator phase noise does not have to be perfect, but it should not be much worse that the Minicircuits VCOs. The cumbersome old-fasioned multiplied crystal is not really needed. So what other options should I look at?

Thanx for ideas,
74,
VK3FLP

See if you can find a drawing of a Peltola connector. This is a very low cost but high performance connector for RG-174 type cable (having a solid center conductor) designed by Ron Peltola at Tektronix and used in Tek scopes and other equipment for many years. You're likely to find some to look at in just about any analog Tek scope from the '70s onwards.

You can reduce the connector number by one half by drilling a hole in your
PCB enclosure and running the >input cable inside the box and soldering it
to the board, then put a connector on the other end of the cable.
All outputs> would have the connector mounted to the box.

I know the lossless feedback based on Dr. Norton (Anzac Electronics) since
1977, when a German M. Martin DJ7VY published in CQ-DL a two stage preamp
for 145/440MHz with BFT66 and BFR34A.
I modified this amp for my thesis on phased array ultrasonic flaw detectors
for lower frequencies. I got much better performance than with the Plessey
SL531. F"=1.9dB, and phaseshift change of less than 1deg. over 102dB dynamic
range until +16dBm O/P.

Hi Ban,
Interesting that you mention Anzac, I picked up an Anzac AM-962 at a
hamfest
many years ago, by the looks of it I thought it might be of the lossless
feedback
style, but I never found any confirmation on the net.
Please help me with your terms.

(1) Definition of F"----?

(2) phaseshift change of less than 1deg. over 102dB dynamic
range until +16dBm O/P.

let me guess
Very little phaseshift with a large increase of input until the output
equals +16dBm??

Thanks, Mike

F" is the noise figure. it says how much the noise gets increased in
comparison with a resistor of in this case 50 ohms.

yes
When you make a phased array amp this is the most important figure, since we want to use zero x-ings to get relevant data. Similar to FM.
This is in general only possible with differential amps, which have at least F"= 6 to 8dB. So this application really appreciated this design.

Hi,
That sounds like a very interesting project. Can I try to persuade you to make it a vector network analyser? After considering making such a thing, I reckon that at least a third of the work is in making the signal source, and so once you've gone to that trouble, you might as well make a VNA which then allows proper calibration, so your return loss bridge etc. doesn't actually have to have good directivity, just be stable over time.

Regarding your question, I think two full PLLs is probably the best solution. If you don't need such wide tuning range for one (or both) of them, you could consider one of the Analog Devices PLL chips with integrated VCO.

Usually in a mixer, one of the inputs is driven hard and the other one is driven weakly. If you drive both inputs of your mixer hard then I guess that in addition to the wanted output you'll see the third harmonic of one oscillator mixing with the third harmonic of the other, giving you a spur at three times the wanted output frequency. What are your plans in order to get a clean output?

Chris

Following is a note I received from a friend who earnestly believes that a Class C plate modulated final requires approximately 200% (rather than 50%) of the final power input to achieve 100% modulation. I am interested in any theoretical arguments surrounding this.
Thanks, Mont - K0YCN

Mont,

Here are the numbers as I calculate them to achieve my goal.

Since Eimac specs are listed in terms of watts output so I will follow that too.
My goal is to be capable of 130% positive peak modulation with 375 watts of carrier output.

The Eimac tube manual says a single 4-400 typical operation at 3000 volts on the plate is 630 watts high level plate modulated carrier output. So, 630 watts X 4 = 2520 watts pep capability.

So, a more conservative 375 watts X 4 X 1.30 = 1950 watts pos. peak. Dividing that by 2 = 975 watts of peak audio output required from the positive producing modulator tube to make 1950 pos. peak RF output.

The 4-125 typical operation indicates 330 watts of AB1 is available. This is a far cry from 975 that I need. On the other hand a 4-400 in AB1 will deliver 1540 watts.

The negative vs. positive peaks will be controlled by a broadcast quality Innovonics AM asymmetrical compressor limiter which I am currently using in the shack.

The simple unexplained rule of thumb I came to understand early in my early ham days is that a 375 watt transmitter requires 187.5 watts of audio for 100% modulation. So, a 4-125, with 330 watts of capability, should be more than what is needed. In practical terms this is very misleading. That is why I been beating a dead horse for three years while two broadcast engineers could not explain why I could barely attain near 100 modulation. Little did I know that I was driving the pants of the poor 4-125's while trying!

Hence, I ordered a custom built filament xfmr that will power two 4-400 modulators. Hope to have all that working in about two weeks.

73,

Soooo...if the modulator is transformer-coupled, how does the DC input to the RF amplifier increase when modulation is applied? A transformer can't couple DC...

Not saying the fellow can't do what he wants, but we need to know a LOT more about the circuit.

Remember, too, that the half-power rule is for sinewave modulation. If you use square-wave modulation at 100% depth, you need as much power from the modulator as the DC input to the RF amplifier. The modulated output is four times the unmodulated power, for half the time, and zero for the other half, assuming an RF stage that responds linearly to the modulation voltage.

For a given modulated waveform, it's easy enough to figure out what the actual power is, and it all has to come from somewhere. If the plate modulation is linear (current is linear with modulated voltage) and the modulation is coming through a transformer, then the average current from the RF deck plate supply must be constant, and the DC power input is therefore constant. Whatever power you put in the sidebands must come through the transformer. But maybe the circuit he's proposing DC couples the modulation voltage, and thus allows an increase in the DC current going to the RF deck.

Cheers,
Tom

You can get DSP-based feedback eliminators that work well and are not outrageously expensive. We use a Behringer DSP110 Shark unit, which you can get for well under $100, and it works well for us. Google "feedback eliminator" and you'll get lots of hits. I wouldn't even think about trying to build one on my own, with such units available. I'm sure there are better ones for more money, and others at similar cost that you should also consider, but I don't personally have experience with them.

Cheers,
Tom

He is not calculating PEP properly. For 100% modulation the plate
voltage must double. That will require 187 watts average power to do
so. A little more with transformer losses.

Average power output from the transmitter will be 375 watts carrier
and 93 watts in each side band for a total of 562 watts average output
with full modulation.
But Peak envelope power will be 1500 watts at 100% modulation. 4
times carrier power.

100% modulation requires the plate voltage to double. Doubling the
plate voltage also doubles the current. So twice the voltage and twice
the current equals 4 times the power for PEP = 1500 watts.

4-125's in AB1 don't produce much power. I would have to look it up
but their AB1 rating is very low compared to some other tube types.

What frequencies will you be working at? At HF, RCA or phono plugs are not perfect and not awfully tiny but they aren't bad and they are EXTREMELY cheap and widely available and easily assembled. The impedance bump from each connection will be obviously there but for most non-measurement HF applications it simply doesn't matter.

The more connections you'll be making or the higher your frequency (especially above 30MHz), the harder it is to argue that you should homebrew it from brass tubing. The cost per connector will go down in bulk, and the reliability you need from each connector will go up. Homebrewing loses a lot of its fun when you spend more time wiggling connectors than actually making or using the circuit. At UHF you start becoming acutely aware of any impedance bumps and the pre-cast connectors take care of all those details for you very nicely up to GHz.

As to cost, SMA/SMB/other small connectors and jumpers with preattached connectors often show up in bulk in the auction places etc.

BNC's will look large if you're laying out PCB's with surface mount components, that's for sure, and RCA jacks aren't a whole lot smaller. There are some variants of phono plugs out there that are smaller but they are not as widely available or as cheap.

Good RF crimpers are not awfully cheap but should be considered in the TOTAL budget.

Tim.

2490. how to test MC1350P based if amplifier?

Newsgroup: rec.radio.amateur.homebrew

Source record: 12491

hello,

In my receiver project I have reached to point where I need to test my
IF amplifier.
It's based on one MC1350P stage.

I know it should give me approx 60dB gain. First idea that comes to my
mind is that I should feed it with very weak signal. Am I correct: if
feed it with lets say..1 microvolt, then 60dB of gain should give me 1
millivolt at the output?

If so..then how can I get such a low level signal (my Hartley
oscillator gives my 1.7 volts PTP).

Any comments?

A metal box with good coax connectors on both ends, containing a
resistive divider made with _good_ noninductive resistors, is the
first thing that comes to mind. You'll also want _good_ coax cable
(better than 99% shield coverage) on the jumpers from your Hartley
oscillator to the divider box, and from the divider to your amplifier.

It probably would be a _very_ good thing to put your oscillator
inside a shielded metal box, too, with precautions to minimize signal
leakage from the cables and from inside the box. Otherwise you'll be
getting some unmeasured leakage signal into your IF amp as well as the
signal from the output side of the resistive divider, and that will
invalidate your measurements.

Good luck, and let us know how you decide to do this.

If you just want to see if it works rather than get detailed performance specifications - put a piece of wire on your oscillators output, put a piece of wire on the input to your amp. See if you can hear it. Increase physical distance between them, decrease length of wire(s) - crude, but will prove it as a "go/no go" test. When you have finished the rest of the receiver, then do some more testing...

Besides, if you dont have a calibrated sig gen, and calibrated instruments to see what comes out of the amp, and its terminated properly, this method is as good as any.....

Seems you could take advantage of all the old Ku & C band
receivers,lnbs and other big dish stuff that people are throwing away,
i
remember the reciever tunes a 950-1400 mhz input span or somewhere
close, from the lnb. Should be alot easier to convert one of
these yardsale items than start from scratch. Ive got a bunch of these
setting around & wanted to put one on the 33cm 902-928mhz
amateur tv band, but the satellite starts alittle higher than that so i
put it on hold for now.

Source record: 12399

It is so simple you can't believe it. It's only Ohm's Law.

The Class-C plate modulated final amplifier is driven hard on its control grid such that it is driven into saturation even when its DC plate volts is increased to twice its normal DC value.

When saturated, the peak RF plate output volts always swing between twice the DC supply volts and some very low value.

The final amplifier therefore constitutes a fixed DC load resistance across the DC supply, which depends on unmodulated RF power output and amplifier power efficiency.

This fixed resistance is also the value of the audio-frequency load impedance across the secondary of the modulation transformer.

For 100 percent modulation, the peak RF plate volts across the tank circuit swing between twice the modulated plate supply DC volts and zero. (Or some very low value.)

The harder the grid drives the plate circuit into saturation, the greater the modulating linearity. The drive limit is reached when any of the tube's electrodes approaches its rated power dissipation.

Eaxactly the same things happen with transistors.

Reg.

Thank you, Reg. My reply would have been much less gracious and not nearly so complete. Probably something like, "Which part of 'constant DC input' do you not understand?" I appreciate that you took the time to write such a nice reply, one that the lurkers may well learn something from.

Another reason, of course, that a tube can't handle modulation peaks is that it's getting weak (or the initial design was inadequate). Seeing the plate current meter wiggle during modulation that's below 100% is a good sign it's time to check the RF output tubes, and as your reply suggests, the drivers as well, though the grid current meter should tell you enough about that. If the filament (cathode) no longer has enough emission, the tube may handle the carrier OK, but not the positive modulation peaks where the current must be about twice as high as with just the carrier. Then the DC current will drop during modulation.

Cheers,
Tom

There are a number of MW DXers who listen only for signals from outside the Americas where channel spacing of 9 kHz is used. In that case, you can have a 1 kw signal from New Zealand sandwiched somewhere between 2 nearby strong 50 kw US stations while using a long Beverage antenna.

I used to have such a setup - I was a mile from WSB 750 with 50 kw with a 1900' Beverage. I needed close to 100 dB of dynamic range if my meory is correct.

I despise Robertson screws, along with the "Clutch head" screws.
Every time I run into either of them, someone has put them in with a
worn bit that strips the head and makes them almost impossible to
remove. I've used surface grinders, drills, and a cutting torch to
remove them to make repairs. I generally replace them with hex head
screws and make sure that I always inspect the bit before I start a job.

********** REPLY SEPARATOR **********

Often a Dremel tool with a thin grinding wheel will allow you to make
a slot and then use a regular screwdriver to remove it.

I've never seen anything with a posidrive screw in it.. They aren't used very much in the USA or at least in Florida... I have yet to need a posidrive screwdriver and I've taken all kinds of things apart in my life.. I consider a good set of torx and allen wrenches a necessity along with a set of sockets and wrenches and of course a small set of jewlers screwdrivers and mini torx bits, hammers, saws, etc...

The funny thing is I never knew what that weird looking phillips bit I had was called until today.

SolderSmoke!
A SHOW FOR ELECTRONICS HOMEBREWERS!

http://www.ourmedia.org/node/211360

Topics discussed in SolderSmoke #20:

-- Mike's rig for 80 QRP
-- Wee Willy DSB QRP rig
-- NE602s for DSB and SSB
-- QST article on Drake 2B receiver
-- Electroluminescent receiver
-- Bill's new telescope and Saturn's moon Rhea

Listen at: http://www.ourmedia.org/node/211360

Background:
Tired of listening to Led Zepplin or NPR on your I-Pod? Wouldn't you like to be able to carry with you the kinds of ham radio conversations that you listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in London, England meet regularly on the ECHOLINK system to discuss their homebrew radio projects. We are making them available as PODCASTS.

You can subscribe to the program, have them downloaded to your MP-3 player, and listen to them at your convenience. To subscribe, just cut and paste this URL into your I-poder (or similar) software. (There have been some problems with this subscription URL -- we are working on this.)

http://www.ourmedia.org/user/36170

If you don't have an MP3 player you can just go to the site below and listen to the latest program (and earlier editions) using the audio software on your computer.

http://www.ourmedia.org/node/211360

Here's the homepage for our show. All our programs are available here. There is also a blog and links to some of the sites and documents we've been

discussing: http://www.ourmedia.org/user/36170

We hope you enjoy the program. Please send us
feedback.

Tektronix used Pozidriv for many years in their scopes. Sometime after
I left the company in 1986 I was told they changed to Torx.

You can recognize a Pozidriv screw because it looks like a Phillips
but has a fine line scribed between adjacent flutes.

Yes, sometimes, or even a fine toothed blade in a hacksaw, but not when you are standing on top of a ladder and struggling to reach the crappy hardware. The moron who built my four car garage used 4" or longer Robertson screws everywhere, and most of the heads were puled below the surface before the #2 bit slipped and chewed up the head. I broke two crowbars removing a dangerous hanging rack he's built to hold plywood above one of the bays. Both were flimsy, and they hung low enough that you could bump your head on exposed screw points sticking an inch though the bottom 2*4 beams. I had to remove and replace a lot of lumber that split because of the way he screwed things up.

Microdyne and Lockheed-Martin both use it, although Microdyne has
moved out of the area.

This is a complete AT 1-6 Tuned input board and switch from the Amp Supply
LK series

Amplifiers. This will fit into the Dentrons also. Have schematics for this.

If you have a Stock Amp Supply or Dentron amp this is what you need.

> So, a more conservative 375 watts X 4 X 1.30 = 1950 watts pos. peak.
> Dividing that by 2 = 975 watts of peak audio output required from the
> positive producing modulator tube to make 1950 pos. peak RF output.

He'd be better off to consider what the modulator is actually doing.
The modulator is DOUBLING the anode voltage for 100% positive peaks.
Say the anode voltage is 1000 volts and current is 1 ampere. The
modulator drives a load impedance of 1000/1 or 1000 ohms. It has to
produce 1000 volts PEAK, which on a sine wave is 707 volts RMS.

707 volts RMS into a 1000 ohm load is 500 watts of sine wave power.

The modulator SINE WAVE power for 100% positive peak is exactly half
the plate input power. This ASSUMES a triode well into class C for the
PA. A tetrode will actually often use a bit less power because it often
must be modulated on the screen (or control grid) and anode at the same
time in order to be linear. The anode of a tetrode or pentode does not
follow square law power rules like a low mu class C triode does.

You can generally consider for voice even LESS power is required, a
good rule of thumb is about 25% of dc input power. So as a general rule
a 250 watt average audio power modulator will modulate a 1000 watt
transmitter 100% on voice.

I suspect he has something wrong with the PA not following square law
power change with anode voltage changes. In order to be linear with
modulating voltage changes the PA has to be well into class C
(switching very hard) and it must, with a terode, have some portion of
audio power applied to the screen (you could do the drive power
instead, but that's tricky).

He could have an audio mismatch or the modulator system might be
incapable of supplying the necessary power which is half the dc plate
input power for 100% modulation with a sine wave. He could have a PA
that does not follow square law power as voltage is changed. There is
absolutely NOTHING wrong with the rule that a modulator capable of
supplying half the dc input will modulate a properly designed PA 100%.

Misdirected feelings - should be towards worn bits of all types that can
mess up all types of screws. Don't blame the screw for the fault of the bit
and the recklessness of the user. Among the three common wood screws here
(slot, Phillips and Robertson), I'll take the Robbie anyday. The ability of
the bit to retain the screw is a big advantage.

Hi Chris,

I am planning to make it a VNA in a later stage. For now, I just need something to check antennas, filters, etc. So a scalar analyzer with a good return loss bridge will do OK.

After some thought & googling around, I'll just use the original suggestion for now. Two identical VCOs + PLLs. So in effect, I am optimising the design for speed & easiness :-). Not for cost or performance...

I am aware that the mixer will produce various combinations of LO & IF frequencies. I am hoping to optimise the power levels to get the 2nd and 3rd harmonic down to -50dBc. That should be enough for return loss measurement. For filter response measurements, this is probably not good enough, so I am thinking about adding a switchable bank of low pass filters at the output. But this is slightly messy, so I'll do it later, and only if I convince myself that it's needed.

The Robertson drive screws are ubiquitous in Canada where they were first made (in 1908) and patented. They are less so in the U.S. due to the fact that, after one business fiasco with licensing the right to manufacture to a third party in England, Robertson refused to license it to any one else, including Ford in the U.S. Ford would not adopt any screw for its production lines for which it could not guarantee unbroken availability, despite the fact that the screw proved to save considerable time in the production of cars. So, they never really caught on there like they did in Canada.

They're catching on. I recently had my deck surface replaced, and nearly all the screws are square drive. (The remainder are Torx.) It's the first use I've seen of them here. They're readily available now at Home Depot and, I assume, other DIY stores.

They have been used in mobile homes for years in the US. I can buy
them bulk at several local building surplus stores. There are several
mobile home manufacturers in the area that dump a lot of leftover or
damaged items.

Pay attention to the placement of speakers. For one, don't try to use mics
in front of speakers. The talker needs to have a zone and loud-speakers
should not "talk" to that zone. People near the talker don't need to have
loud-speakers to hear him/her, so if there are some, disconnect them. They
should also "point" where the sound is needed, not oriented because the
mounting is easy. You have to walk around and see where the loud-speakers
are needed and have them there, but not everywhere. I obviously don't know
if this is the case for you, but churches tend to have PA systems thrown at
them rather than designed.
You can "notch" the preferred frequency, for a few db of feedback margin,
with an equalizer. However, when you notch the primary frequency, the next
pops up a few dB down and you can keep chasing them until you have reduced
the gain all thougth the spectrum. Plus, just move a foot or two and the
path changes and the preferred frequency changes.

I am unfamiliar with DSP feedback eliminators, but the job should be easier
if you start at the source (of speaker / mic proximity)

You can try an equaliser in the amplifier input feed, and try to notch out the worst feedback frequencies. This will work, but is quite a limited approach.

The best method is to use a frequency shifter that moves the whole audio spectrum a few hertz up or down. Surrey Electronics here in England make such a device, and it's transparent in use - you can't hear it working, but feedback problems are almost entirely eliminated.

We had the same problem in our local Church. The 'system' involved a
couple of bass guitar speakers hung on the wall, a guitar amp and a
not-so-cheap omnidirectional mic at the lectern.

The whole thing 'rang' like a bell at the slightest provovation.

The Church is in a smallish room - probably 30ft x 50ft - with a low
ceiling - and partly divided half-way by a couple of stub walls -
which made it very hard for people at the back of the Church to hear
wht was being said, unless the speakers at the front of the church
were turned up loud enough that you got feedback...

The solution was to replace the lot ! - but as a lot of it was
homebrewed it didn't cost a fortune.

The lectern mics were replaced by a pair of electret boundary mics
with a cardiod response (didn't pick up sound from the direciton of
the speakers. The giant bass speakers were replaced by two pairs of
decent 2nd-hand hi-fi speakers - one pair near the front of the Church
and the other pair at the stub walls, facing backwards.

The amp was replaced with a custom unit, containing three (mono)
40Watt IC amp modules - one for the front speakers, one for the back
speakers and the third one for future use to drive an inductive
hearing aid loop. Volume is independantly controllable between the
front and rear speakers.

This, of course, is a specific solution for our specific situation.
What you probably need to do is start with a simple plan of your
Church - showing the areas where mics are needed, and where you can
put speakers. If possible, you'll find that multiple,
independantly-controllable speakers will allow you to keep the sound

level high enough for intelligibilty without getting feedback - you might find that you only need amplification 'at the back' of the Church....

Look closely at mics - the closer and more directional the better - may even be worthwhile using radio mics, if your people can be trained to use them. The notch filter will work - but it's only a 'band-aid' solution - get the accoustic design right and you won't need one !

Hope this helps

I guess that you could build a speicific notch into the mic pcb - but
that'll only work if the feedback is at one specific (resonant)
frequency. I think the best filtering systems are 'adaptive' - in
that they can spot feedback happening and can drop a tunable notch on
top of it in real time. Complicated though - and tends to be done at
the amp, rather than at the mic.

All the stuff in the other post applies though - look at the system
first......

Something that can be built with 1 chip just to experiment for now.
From what I read, regular fiberglass boards don't work well above 1 GHz.
Where do you get teflon boards?

Cool, how much are these cheap receivers?
Can you use them for a radio telescope @1420MHz?
These would need to recieve AM mode.

> From what I read, regular fiberglass boards don't work well above 1 GHz.

That's a bit of an overgeneralization. We routinely use "generic" FR-4 to 3GHz, and you'll find that many wireless routers at 2.4GHz do as well. As long as the paths are relatively short and you're just using the board to get a signal from point A to point B, it works pretty well.

The folks who suggest you use Teflon or other high-quality board materials are probably thinking of building distributed circuits on it -- stuff like filters, where the board's loss (its Q) significantly impact how good your filter's response is. (Building something like a bandpass WiFi filter -- ~25MHz wide at ~2.45GHz -- on FR-4 using coupled lines is probably not such a hot idea -- this would be a good test case to simulate.)

> Where do you get teflon boards?

All the decent-sized board houses (e.g., Advanced Circuits, DDI, etc.) have low-loss board materials available. Nelco (http://www.parknelco.com/) and Rogers (http://www.rogers-corp.com/acm/index.htm) are two of the big players here. We have many boards done in Nelco 4000-13, which is a "mid-loss" material... only somewhat better than FR-4 when it comes to absolute loss, but considerably better when it comes to the specs not drifting over process, temperature, etc., all at a relatively small pricing premium.

If you can afford it, by all means, get low-loss boards. However, in many cases in the low-GHz area you end up with more loss from items such as coax cable, connectors, impedances mismatches, etc. than the PCB material itself.

2530. Regen Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-04-27 00:27:47 UTC
From: dconley@lawfacts.com
Message-ID: <1146097667.588709.301120@v46g2000cwv.googlegroups.com>
Source record: 12431

I was wondering if ya'll could help me with an issue that I am having with a regen receiver that I built.

I built the usual regen circuit with two stages of audio coupled with interstage transformers. The regeneration is controlled by a pot which varies the plate regen voltage. The grid leak combination is a 6 Mohm resistor and 45 pf cap.

The regen and first audio stage tubes are 1H5GT triodes. The second stage audio tube is a 1C5GT pentode. The filament voltage is 1.4 volts, plate voltage is 90 volts and screen voltage for the 1C6GT tube is 90 volts. The set easily and cleanly drives a speaker.

I have wound my own coils which cover the broadcast band up to about 15 Mhz.

I really like the way the set operates and it is very sensitive.

My problem is that the regeneration often fades out (the radio essentially goes dead) and I have to touch the grid of the regen tube to bring it back in. I had originally built this radio only having one stage of audio and I did not have this problem with that version. It's kind of like the charge on the grid builds up too high and I have to "drain" it off with my finger. Sorry for the bad description--I'm obviously not an engineer.

I did try various other combinations of the resistor/cap for the grid leak including the classic 2.2 Mohm/150 Pf combination and it still has the same fade out problem. Therefore,
I decided to stay with the higher resistor/lower cap value because the receiver works better at those values (when it is working).

I usually power the radio with a battery eliminator, but the same problem exists even when I use only batteries. For a ground, I am using the mains ground.

I'm hoping that you can give me some ideas to fix the problem for what is otherwise a great receiver.

Thanks to all of you in advance.

Dan

Hi Dan,

Have you checked that your 6M ohm grid leak is actually 6M ?

It does sound like a charge build up on the grid. Does the RF anode current rise or fall when the radio goes dead ?

Are there any components attached to the grid that could be breaking down slowly - capacitor, maybe even valve base.

Have you tried replacing the valve base ?

Have you tried a different valve ? Maybe broken or cracked valve bottom (paxolin to valve pin).

Stick the whole unit in the oven (on low) and dry it out for 3 hrs - moisture getting in somewhere ?

Does sound weird and interesting.

Regards,

Mark.

Source record: 12433

Hi Mark,

The resistor is definetly 6 Mohm, but you bring up an interesting point about moisture.

I have noticed that the set seems to fade out more during rainy or high humidity days. I didn't even want to mention it because it sounded silly, but I did wonder if humidity might be a factor.

On some clear, dry days, I have not had any trouble at all. So, maybe you have something there.

I will carefully go back over the items you mentioned and maybe replace all of the caps in the circuit. Replacing tubes hasn't made a difference. Thanks.

Is it a single pager?
I once watched the local pager band with a spectrum analyser, and there were at least a dozen pagers coming on and off at different times and on different frequencies, the lowest of which was below 149MHz. (This is in Australia) Several of them actually produced IM products between them that were *not* from the spec an front end. I surmise that these are actually produced locally. Apparently transmitter output stages can produce these when there are antennas located close to each other (within a few metres) on the same tower. Others have proposed a stub configuration - you may have to consider beefing up the front end for better strong signal handling as well if there are several signals.

There are a few other factors here. The big one ne is that no real
tube or transistor swings ALL THE WAY to zero volts at full current!
Another is that for the final to be truly ohmic would require that a
near-Class E or F condition, with the grid swinging from cutoff to
saturation almost instantly(as in a square-wave drive, sometimes used
in broadcast AM Class F setups).

The next condition is that the current drawn through the load at 2X
supply voltage must not cause the tube or transistor's bottoming
voltage to more than double! In the real world, this means that the
current(loading) must be backied off from CW conditions for any
particular device, just as the voltage must be. If you load a final
for maximum output at carrier, guess what-you will be lucky to see 30%
upward modulation with MOSFETS or somewhat better with tubes!

As a result, you want to design the final as though you were building a
CW amp to operate at double the supply votage with so short a duty
cycle that dissipation wouldn't overheat the device first. The active
device must not at any time be an impediment to drawing full AC current
through the load.

OK, here's what my experiments with the IRF 510 MOSFET uncovered at MF:

1: this device can make 55W a part at 17V, but for even 90% modulation
you must cut
loading to 37W a pair. Similar current derating should be expectd
from tubes, bipolars,
etc.

2: MOSFETS tend to lose drive as you raise the supply voltage. Here's
why-in Class C,
You are severely compressing voltage gain. As you add B+ in
modulation, voltage gain
increases. This increases the effect of Miller(reverse transfer)
capacitance). Any non-
neutralized common-cathode device will have this problem-or at the
other extreme
could oscillate on peaks! MOSFETS are lossy in all interelectrode
capacitances, so
even with "unilaterialization" in which both R and C(not just C)
are balanced, drive loss
in the resuloting "bridge" circuit" still rises with the supply
voltage. Since MOSFETS
cannot be driven beyond maximum safe gate voltage, you therfore
will need to modulate
the driver as well, or apply a few volts of gate modulation as an

alternative.

IF YOU DO NOT DO THIS, you will have 100% downward modulation real easy,
but as little as 30-50% upward modulation, with a real serious carrier shift problem
and audio that sounds like $%^&.

3: I've heard bipolar transistors also need some base modulation to follow collector
modulation properly.

4: Tetrodes have a similar problem, but in a different way. Here, the problem is that plate
voltage and evn bottoming voltage have little effect on plate current, and real-world
tetrodes and pentodes require some screen modulation to propely follow the plate
modulation.

5: Triodes with their low plate resistance may well give bottoming voltage in proportion to
current, and therefore to voltage. This is a desirable condition, but the only common use
of triodes today is in grounded-grid, where 100% downward modulation is impossible.

One of the nice things about those Class E and F, true ZVS finals for AM is that they give a far more ohmic modulation curve!

Hi All,

I'm looking at the pcb on page 8 of the following;

http://www.avagotech.com/pc/downloadDocument.do?id=3369

(It is an HP application note #1049)

The way I figure it the pcb is 4" x 4" and the in/out and bias
traces are .125" wide, necking down to .050".
The vias compute to .170".
Does any of this make sense for a surface mount pcb with so
few parts?

What is the maximum freq. for the 1N5711?
I like something that works to 2.4GHz at least.

JJ

2540. Plastic Antenna Insulators

Newsgroup: rec.radio.amateur.homebrew

Anyone ever try using plastic drywall anchors for yagi antenna insulators?
I'm wondering how they will hold up to UV and the weather in general.

Thanks,
RoD

2541. Checkin' out dummy loads with a VNA...

Hi all,

I'd like to see what this new dummy load I just bought on e-bay looks
like under test at its purported frequency limit of one Gig.
Problem is, all the documentation I have for my VNA shows devices to be

tested having *two* connectors (an 'in' and an 'out' if you will) like
filters for example. I can only connect to the *one* connection that
dummy loads typically have, since it'a a termination device rather than

a through one like a filter or attenuator. Does that mean I can't
analyse its
characteristics? Or is there a work around/special cable configuration
that would solve
this problem?
Thanks,
<clueless paul>

Tell your VNA you want to measure S11; it won't even touch the second port (feel free to hook it up to a high-gain antenna and point it at the nearest cell phone tower in your neighborhood...)

Unless your VNA is 20+ years old, it'll be happy to display the S11 measurement in the form of a Smith chart, real/imaginary impedances, VSWR, etc...

A quick and dirty one would be to use a resistor from VNA-out to dummy load, then another from dummy load to VNA-in. 50 ohms or less. With next to nothing reactive, of course. All nicely RF fashioned, chip resistors maybe. It's not going to be matched but you can have the analyzer do the math to calculate out the dummy load. Mind the power limits.

Sometimes I do this with an HP resistive splitter when the impedance analyzer is down (like it is right now, again....%*&#!!).

Hi Paul,

I don't mean to pick on you, but... you really should become more familiar with VNA measurements in general. You should be able to find documentation on the web; try the Agilent site for example, and look for VNA ap notes. I downloaded some recently, so I'm pretty sure they are there. A VNA is a wonderful piece of test equipment, but it won't give you answers you can trust if you don't understand it. I would trust what they tell you (or similar from R&S or other reputable manufacturer) more than I would trust replies here to be not only accurate but complete.

For example, you should understand that your dummy load could be considered a two-port device where S21 and S12 will be very low--hopefully vanishingly close to zero. If you connect it to port 1, you should get a valid indication of S11. You should expect S22 to be unity or very close to it, if that port is left open or shorted. (But why would you even bother to ask for S22, or S21, or S12?)

But there's another problem here. HOW do you calibrate your VNA?? You ideally should have a precision short, a precision open, and a precision load--best if you have calibration data for the loads. If you measure your load, how will you know whether an imperfect S11 is due to the load, or to the VNA? Of course, it will be to some extent both, but it would be nice to know that the VNA is accurate to within some tolerance.

Cheers,
Tom

2545. Re: Size of pcb for pin diode switch?

It was probably just a convenient size...but FWIW, if I measure the traces compared with the SOT-23 size (lead spacing, for example), I get that the input/output traces are 0.054", plus or minus a bit. To be 50 ohms on an FR-4 board, that must mean the distance to the ground plane is about 1/32 inch (which seems quite reasonable), and the board would be about 1.8" across.

Cheers,
Tom

It depends on the plastic material - it's worth doing the microwave oven
test before using it. I find that PVC that's OK in the microwave oven
usually stands up to UV well.

Okay guys, thanks.
Yes, as you've surmised, I'm only just beginning to get to grips with this complex piece of kit and there is *much* to learn indeed. In my defence, I have to say although I purchased this thing 5 months ago, I've only now been able to assemble the ancilliary cables, loads, splitters and whatnot to be able to check it out properly. All I could do back in December was to switch it on and check for signs of life. Now, however, things start to get rather more complicated (but hopefully stimulating, too).

WSQT wrote:
> There are a few other factors here. The big one ne is that no real
> tube or transistor swings ALL THE WAY to zero volts at full current!

It does niot have to be at full cuttrent, and it actually cannt be at
full current or the modulation will not be linear.

The power has to follow a square law relationship with voltage change.
meaning current is twice when voltage is twice, current is zero when
voltage is zero.

This is why the anode impedance is stable over a wide range of anode
voltage, and why PEP power is four times the carrier power in a good
clean plate modulated transmitter.

> Another is that for the final to be truly ohmic would require that a
> near-Class E or F condition, with the grid swinging from cutoff to
> saturation almost instantly(as in a square-wave drive, sometimes used
> in broadcast AM Class F setups).

Class F is an invention to describe certain circuits. It technically
fits the definition of class C.

RCA and other manufacturers used "square wave" drive in class C
amplifiers in the 40's and 50's. The method of obtaining the square
plate current waveshape was the addition of third harmonic resonators
or traps in the grid and anode circuits of low mu triodes. Allowing the
3rd harmonic inherent in the tube switching from cutoff to positive
grid voltage by not "grounding" the grid or anode at the third harmonic
caused the PA to switch into and out of conduction rapidly. Typical
efficiencies were in the mid 90% range.

It was called class C back then, and it techincally fits the
description of class C.

When the tube switches very hard, the linearity of anode power input
(and RF output) follows the desired square law change very well.

> The next condition is that the current drawn through the load at 2X
> supply voltage must not cause the tube or transistor's bottoming

> particular device, just as the voltage must be. If you load a final
> for maximum output at carrier, guess what-you will be lucky to see 30%
> upward modulation with MOSFETS or somewhat better with tubes!

What does that have to do with plate modulated stages?

The anode operating impedance is nearly constant throughout the full audio cycle, and the ratio of E/I tracks very well regardless of load setting in low-mu triode class C modulated stages.

The tetrode is a problem only because the anode does not follow a square law power change as voltage is changed. This is because, as you pointed out, the anode current is controlled by the screen voltage more than anode voltage.

In a tetrode or any other screen grided tube, some audio has to be applied either to drive, control grid, or screen voltage. This is to ensure anode current tracks a square law relationship with modulation voltage, plate operating impedance is reasonably constant, and peak power is four times carrier power.

No matter how I load a class C plate modulated triode, modulation remains reasonably constant. It is only in multigrided plate modulated tubes that modulation can be seriously affected, since screen current and the effects of screen voltage and current change can vary drastically with load setting.

The issue the orignal poster missed was how the class C PA behaves as voltage is changed by the modulation transformer. Power output should square as voltage is doubled, but that's tough to do in a tetrode unless screen operating conditions are controlled and the circuit applies audio voltage in the proper relationship to anode voltage in a grid.

Most of the AM pages I see don't really understand the importance of that, and think just throwing a high inductance choke in series with the screen makes the tube follow square law rules as modulation voltage is changed.

The newspapers and journals are full of information about warrantless wiretapping and eavesdropping. What many people do not realize is that the type of eavesdropping occurring for national security purposes is vastly different than the real world of eavesdropping and wiretapping utilized for industrial espionage, law enforcement and by your local private investigator or tech-guy that has crossed the line into illegal eavesdropping.

Now, the realistic world of eavesdropping has been thoroughly exposed in the new two-hour video called "The Red Balloon". Already recognized as the best Issue Awareness Video in 2005 at the international Aurora Awards and given a 5 Stars review in the March issue of Security Management, The Red Balloon presents the government and industry statistics about industrial espionage and eavesdropping, and how big this problem really is. It also reveals the different types of eavesdropping devices used with illegal wiretapping and eavesdropping and the novel techniques utilized by both professional and amateur eavesdroppers.

If you are curious about the eavesdropping industry then you simply must see the powerful informational video presented by one of the world's most recognized experts in the field. To learn more you can go to http://www.tscmvideo.com

Hi Tom,
Thanks for your info, I recomputed using the lead spacing and got about
the same 1.8" as you say. My first computation used the info from the
article
that the diode spacing is 0.27" apart, this is how I got 4". I'm still not
sure
about the size, because using either computation I should get the same
answer.
You are correct on the 1/32" FR-4, it is somewhere in the article.
If I make this circuit it will be a 75 ohm pcb for a cable tv switch.
I'll need to look for a stripline calculator.
Mike

Just curious, which VNA are you using?

Tentec has a really nice one. Only goes to 100MHz but for around $700 it seems like a good deal. Some of my clients could have used these but unfortunately this VNA does not seem to have an industry-standard calibration scheme. Wish they did, then I could probably get rid of my heavy 4191 in the lab.

I would think one advantage of square drive would be it is nearly
impossible to strip the drive hole, unlike Phillips and especially hex
(Allen). I think I'll scout around for some for my next building
project in 6-32, 8-32 and 10-32.

Who knows, might even try metric sizes.

I'm amazed with all the times I've posted it that there is _anyone_ left who hasn't downloaded RFSim99. It's a freebie you should be able to find with a quick Google search. Besides being a useful simple simulator, it is also a toolbox: impedance calcs for L and C, transmission line calcs including microstrip, attenuators, couplers (hybrids), ... Also includes a "spur search" program for calculating higher order mixing products.

BTW, I also used the 0.27" spacing which I interpreted as center-to-center for the diode pair on either side...I used it as a quick cross-check. It told me the board is about 2" square. Scaling like that, if you get within ten percent you're probably doing well. It's a shame they didn't put the scale in the drawing, though.

Cheers,
Tom

The fan on the power supply in my Kenwood TS-940 section stopped coming on. I replaced the motor with a new one. The thermistor would kick on the new fan when I placed a soldering iron against it. I put thin layer of thermal grease between the thermistor case and the heatsink and screwed it firmly to the sink. The fan refuses to come on with this configuration. Just can't get enough heat into the thermistor I guess.

Do thermistors go bad or what? I'd like this thing to come on at a lower temp anyway. Does anybody know of a replacement which would do that? I have zero data on the factory thermistor...I don't have a temp probe to check it myself either.

-Scott.

Well, I've never seen them in the sunny south. I'll just keep using Torx and Allen screws, thank you. The Allen screws have served me well since the '60s, and the Torx for over a decade. maybe you need them up there to be able to hold on to the screw with your hand shaking while you try to get it started into the threads? ;-)

Yes they go bad. Ask any old TV repairman how many hundred
thermistors they replaced in the degaussing circuits.

Mm, yes - TV set PTC's do go crook, but thats because they get full mains voltage at many amps across them. And it takes a few years to do it. And its usually the heat generated dry joints on the main board anyway that winds the set up in the shop.

Easy method - repalce the thermistor, in the meantime stick a fan at the back of the radio so it doesnt melt down. Or wire the fan hard on always....(Hint - put your hand on the heatsink/case, if its too hot to touch, its too hot.)

If you want to get technical, then its time for logical fault finding. There are 3 things that can go wrong. _ the fan, the thermistor, the switching cct. You have replaced the fan. The thermistor DOES switch when it gets heaps of heat. Leads me to think the switching cct is faulty.

BUT to prove - disconnect the thermistor from cct, stick your ohmeter across it, apply heat. Should be fairly rapid change in dc resistance - and use a hairdryer, not your soldering iron. If the change is only a few ohms, then its faulty - replace. Otherwise, on to next step - check out switching circuit of controller.

This is a "bread and butter" fault, shouldnt be too hard to fix.....

Andrew VK3BFA.

Dan wrote that the regeneration in his receiver is controlled by a pot which varies the plate regen voltage. I saw this method was popular mainly in old books (ARRL from 30's and 40's for example) but later the most popular became a control on the screen grid. Does it mean, that the second method is better ? Why ?
Sorry if my question is naive but I'm beginner, especially in tube stuff.

Actually my regen tube is a high mu triode (1H5GT), so there is no screen voltage to control. A lot of folks like to use throttle caps to control regen, but pots are easier to mount and don't take up quite as much space. (I know that a lot of people will disagree with me here on my choice).

My second audio tube is a pentode (1C5GT) and I use a one meg pot on the grid to control the volume for the set. I also have a 10 ohm pot on the first audio tube (1H5GT) filament which also helps control the volume and nulls out hum.

In case you are wondering why I chose these tubes, they are the tubes that were used in the old battery sets and have low battery drain (although I use a battery eliminator anyway for my power source). They are also very cheap and plentiful.

I also was able to "steal" the engineering from the old battery radio schematics to figure out the capacitors and resistors to use in the audio circuits to make the output sound good. I'm basically too lazy to learn the formulas to do my own calculations. The set sounds as good as any battery set that I have ever heard.

This particular combination of a 1H5GT first audio stage tube followed by a 1C5GT second audio tube was used in a lot of battery sets. It also made selecting the output transformer easy to maximize output to a 4 ohm speaker.

Dan

It's an HP 8754A (4 to 1300Mhz) and luckily old enough to be reasonably serviceable and repairable!
This is just as well since there is a fault with the rectangular trace, which just appears to 'flatline' with nothing visible other than the sweep + markers. So no nice bod plots of filters, I'm afraid. However, the polar and phase displays seem absolutely fine. If I can just get that one fault fixed, it'll be a great piece of test gear to have around. I've never worked on anything this complicated before, though, so it'll be something of a challenge!

2569. 13.8V high current power supply

Newsgroup: rec.radio.amateur.homebrew

Source record: 12370

Hi all,

You may recall me mentioning I was thinking about adapting a 24V PSU
for use at 13.8V for powering up mobile HF rigs and stuff. I had some
spare time yesterday and took this thing to bits for a better look
inside. It turns out the mains transformer has several secondary
tapping points. I discontected the DC-stab/reg side of the supply
circuitry and reconnected the secondary tapping points to lower voltage
tappings.
Now I measure 16.8V after the transformer's output has been rectified
and applied across the *big* electrolytic. This is under no-load
conditions. Now, is that 3V enough 'headroom' to use up in regulation
and stabilisation for 13.8V final output if I throw the old 28V
reg/stab away and build something from scratch? There are 6 pass
transistors plus a driver (2n3055) already mounted which I plan to use
in the adapted version, so basically I'll just junk the existing
control board and re-use everything else. Any observations/tips?
Thanks,
P.

This is probably a stupid idea for some reason that's beyond me right now, but how about losing the extra volts with a series of diode drops? Provided the diodes were high forward current types with adequate heat sinking. I know it wouldn't be as stable as a proper design, but would it work well enough to run a mobile 100W rig?

I think you'll end up with lousy regulation and
a ripple problem.

I would cobble together a simple, say lm317 regulator to drive your series
pass driver and see what you come up with under some small loads. You may
be ok with that big transformer. The power supply I built uses 4 2n3055 in
parralel like what you have. Have fun.. JTT

That looks like a problem in the digital section. Just hope that none of the EPROMs suffered a memory loss. I am not sure whether they'd report a checksum error in the 8754. I had found one that had become unseated on another analyzer and the instrument produced only garbage output but reported nothing on self-test. That disappointed me a bit. The only reason I found the cause was that I opened it and looked at it long enough.

Complicated they are. However, while on the troubleshooting trail in my HP4191 I sometimes came upon a large conglomeration of discretes and banged my head, asking myself "Why didn't they do that with a uA733?". And on the directional bridge they seem to have left about 10dB of dynamic range on the table for the test channel versus the ref channel. I'd have put a wee amp before the sampler.

Paul -

An ideal secondary voltage is about 5 more volts than you want to regulate.
Let's say that it is 13.8 volt finished.
Then and ideal secondary voltage would be 18 or 19 Volts AC on the
secondary.

Using 6 pass transistors (2N3055) - The 2N3055 is good for an intermittent
current or amp draw of 10 amps.
A heavier one that is often used for 13.8 VDC supplies is the 2N3771.
This one is good for 15 amps intermittent. Both of these are NPN type
transistors.
These are placed in a parallel circuit, if more that 10 amps surge, is
required.

Heat is the biggest enemy of our power supplies.
Keep them cool, use well sized heat sinks and they last a lot longer!!

You will find that the LM723 is the most used regulator IC for commercial
linear supplies -
it has been around since the 1970s !!

Here are some web site articles and references for both your design and building.

Thanks, Joerg.
I think this item pre-dates a lot of this digital stuff; I doubt
there's a single eprom in it - and no custom chips, either!
It was built in about 1980 and doesn't go through any self-testing
routines. One has to carry out manual tests oneself. This wonderful
simplicity should hopefully enable me to keep it running indefinitely,
once I can get it fixed. Serviceability is one of my main criteria when
choosing an item of test equipment.

2577. Re: Regen Question

Newsgroup: rec.radio.amateur.homebrew

Source record: 12378

The regeneration control either varies the amount of feedback
(throttle cap, movable tickler coil, or pot across the tickler coil)
OR varies the gain of the valve (or solid state device) by varying the
plate voltage (pot or series resistor), screen voltage (consider the
screen of the tetrode or pentode as the plate of the triode and the
plate of the tetrode that of a cascaded second stage), or grid voltage
(yes you can also add negative bias to the grid to lower the gain,
rarely used in a regen using tubes but the ONLY way with FET's).

If the variable gain method is used, then the tickler coil must have
JUST the right number of turns so there is JUST the right amount of
feedback for regeneration to start when the valve (or other active
device) is operating at the optimal gain setting for detection. If
TOO much feedback is provided the gain of the detector must be set
so low that poor sensitivity results. Also adjustment of the regen
will be tricky. If too little feedback is provided regeneration may
not happen or the detector gain will have to be so high that the
detector will be unstable.

For some reason most triodes seem to operate as detectors with
about 30-50 volts on the plate, and pentodes with 20-50 volts on
the screen. Using a regulated supply for the detector is a good
idea, especially if you want to try and receive SSB signals.

The fade out problem with your regen sounds familiar, I had this problem
on an old AA5 radio. It would stop playing after a while and came back
if I touched the signal grid lead (antenna tuning cap hot side) of the
12BE6 tube (I actually held one end of a .01 cap and touched the OTHER
side of the cap to the grid as it was a hot chassis set). Weird!

Maybe I had a bad cap in the agc circuit, not sure.

==========
There as an exellent design in RadCom Oct 2001 ,pages 34-35 by OZ1XB ,
with a LM317 , TIP32 (PNP) and 2xBUV20 (NPN) ,with the latter
replacable by 4x2N3055 or whatever you have .
Simple,rugged ,reliable design.
It incorporates sensing lines ,ensuring the full set voltage under all
load conditions at the consuming apparatus.

You're probably right! I did actually try to rip the heating element
out of a 2kW electric fire to use as just such a test load, but the
manufacturers had used some really devious sort of screw heads to keep
the two casings together. :-(
Failing some serious resistance wire, the only other 'to hand' option
is to hook up the HF mobile and key-up; but I don't have a sufficiently
gutsy dummy load or antenna to dump 100W into, I'm afraid. :-(

>
In general using a higher grid resister and smaller capacitor results
in increased selectivity and sensitivity with a loss in large signal
handling ability. Visa Versa for smaller grid resister and larger
coupling capacitor. Also the grid resistor can go across the capacitor
or from the grid to ground. If the grid coil's cold end is NOT grounded
the latter arrangement is required. In early tube manuals the
recommended grid leak resistance was usually 1-2 meg ohms, with a
capacitor value of 100-250pf. You have to watch the time constant
there or you might end up with 'super-regeneration' where the tube
breaks into a high frequency (ultra-sonic that is, around 10khz)
oscillation.

I have a new pair of 1N23F in unopened packaging. These are the
almost the same (but 1 dB better NF) diodes but in the DO-22 package.
In this package, the cathode is connected to the pin and the flange is
non-removable.

If these will work, make me a reasonable offer.

Is there a place on the net, in a book, etc. that I can see examples & diagrams of a coax bulkhead? Perhaps someone on this NG constructed such a device & wouldn't mind sharing his plans.
My house sits on a slab and I would like to run about 4 or 5 coax cables, rotor cable, AC & DC source all going from the shack to my tower. In Florida lightning is a major concern so the bulkhead will have to have coax (gas arrestors?) & other types of arrestors. All this, of course, should be grounded to a copper ground rod. I would like this outside "box" nicely & neatly dressed & labeled so it's easy to disconnect & is not an eye sore. I searched the Ham books and many Internet sights to no avail.
Anybody? Thank you.

>
> the key thing is enough load to simulate a radio and parallel lamps
> of sufficient power will do that safely.
==========
In the absence of car bulbs , a good dummy load to test a power supply
unit is to take a length of galvanised fence wire of say 1mm dia or larger.

For a 13.8V-20A supply the load resistance needs to be 0.7 Ohms.

Send a current of 1 ampere through the wire and measure the voltage with
a DVM. Subsequently slide a crocodile clip along the wire until the
voltage measured is 700mV ,then you have the correct length.
Coil the wire and connect to a "chocbloc" connector.
Place coil in a plastic bucket filled with water.
Although tap water is somewhat conductive the overall resistance will
probably not decrease significantly. If it would you could make the wire
resistance somewhat higher (longer wire).

An alternative method would be using a roll of PVC insulated copper wire
of sufficient diameter determining a 0.7 Ohms resistance with the above
method. Again use as dummy load placed in a bucket filled with water .

Hi Joerg,
Well I'm sorry to hear that. As an analogue guy, I don't much care for PROMS and stuff. I can fix up anything analogue in good time, given a schematic and a decent range of test equipment, but am off my territory with digital stuff. But I'm still not sure what the problem is here. Are you saying spares for the digital parts are hard to obtain or rather that the encoding on those chips may be hard to reprogram?

"Other tubes I've used (12BA6) that resistance could be 10meg it
behaves
well where with a 12EK6(12v space charge tube) was happiest
with 5meg."

I'm thinking of putting a 10 ohm pot in series with the filament of the regen tube to see if making the filament less negative in relation to the regen grid might work, maybe also using a bypass cap across the pot. I don't have one right now but I'm going to play around with different resistor values (like around 3 ohms) until I can order one.

Did you think about doing something like this when you couldn't get your 12EK6's to work with a 10 meg resistor?

Not sure yet what is broken. The analog sampling stuff and all seems to work but is reads out garbage. The PROMs are really old style. They look posh with gold plating and all but I guess that non-programmed spares would be next to impossible to find. But again, maybe they are still ok. Hopefully...

Simple Tone Detector

I'm looking for a SIMPLE circuit to detect the presence of a tone - any tone in the audible range.

My quest: Consider the poor radio dispatcher, sitting there wearing a pair of headphones when the next town / county over tones out an ambulance or fire department.

I'm looking to be able to detect any audible tone and use the results to decrease the operator's headphone sound level during the tone.

I have already tried a DSP tone elimination and found that:
1) It's too effective: I need do decrease tone volume - not eliminate it.
2) Way too complex and expensive for the seemingly simple task.

The circuit needs to be compact and inexpensive - connected between the dispatch console headphone jack and the operator's headphones. It must NOT interfere with normal speech!

I have spent several hours online seatching and came up empty. Any thoughts or suggestions?

Bill Powell

Hi Bill,

One idea: Have an audio voltage controlled oscillator, locked to the audio input with a phase locked loop. I'd try the 4046 chip. Add the locked VCO output shifted by 180 degrees to the audio. Set the amplitude of the counter-tone, so that it doesn't completely cancel the output, but just attenuates it. The PLL will keep the shift constant. You'll also have to detect when the PLL is not locked and remove the counter-tone on this condition. No idea how well this would work... but I'd cost only a few $, for the 4046, an opamp or two and some Rs&Cs.

Anyway, just an idea.
Cheers,
VK3FLP

Nah. Something plugged, and your grid leak bias wasn't leaking any more.

You could build a circuit using a 567 tone decoder IC, but the problem is
that you will first need to know what freq the tone is. Still you could use
multiple tone decoders, feeding to a muteing circuit. If you can specify
the tones you want to mute, we may come up with a circuit to help. The 567
would output to a relay that would simply mute the audio only when the tone
is present. JTT KF4HUF .

Sounds like a good start

Don't forget the 6 x Emitter ballast resistors (each should drop 100mV at full load), so maybe 10 milli ohms each (short length of electric heater element ?).

May need a fan to keep the heatsink cool.

You probably also need to mount the driver transistor on a heatsink.

Regulation using an LM723 or similar. There should be plenty of detailed designs out there - also see the Nat Semi application notes on the subject.

See http://www.national.com/pf/LM/LM723.html

Use a CMOS switch (4016 or 4066) to mute the tone.

> No idea how well this would work... but
> I'd cost only a few $, for the 4046, an opamp or two and some Rs&Cs.

It works really well - I used to use this method to remove the 96 kHz
(approx) interference in "scrambled" cable TV signals.

....noooo, you should not have any problems! these two connectors
units are actually attenuators, not loads. loads have only one input
connector.
ctually you can measure all the important characteristics of the load
by applying power through some kind of directional coupler an measuring
the applied (incident) power and the reflected power by using the VSWR
formula you can calculate the input real resistance in order to obtain
a curve relative to frequency. of course, in order tomeasure the
complex impedance, you need acces to equipment capable of measuring the
phase angle also, like a vector impedance meter or a vector network
analyzer: you measure reflections caused by mismatch in a 50 Ohms
environment, and translate them in complex impedance values.

Has anyone re-wound a power transformer with good results?
I have salvaged some big transformers from microwave ovens, and cut the secondary winding out of it. Then re-wound it with 14 guage till getting enough turns to produce about 20 volts. Problem is the thing gets hot even without a load on it.
Is there something I am overlooking? Thanks.

Hi James,

Yes, there are shunts, which need to be removed. There is/was an article about how to rewind microwave oven transformers. It was in an ARRL QEX or similar magazine.

You can find a copy of that article in the Files Section of the yahoo rfamplifiers group.

http://groups.yahoo.com/group/rfamplifiers/

Pretty much shows you what needs to be done.

Hope that helps...
cheers,
skipp

I found the same thing when I rewound one a few years back.
Apparently the primary is saturated so it will draw 4 or 5 amps with
the secondary loaded or unloaded. This provides some voltage
regulation.
I should have taken a variac and ran a V/I curve from 0 volts to the
point saturation occurs and the current starts to rise. That would
prove that the transformer operates in saturation.
My microwave is rated for continous operation at full load, so
apparently the transformer doesn't get hot enough to let the smoke out,
but it does get hot.

How about a simple AGC circuit. You could make the detector more sensitive
around the tone frequency (with a BP filter) so it will reduce gain more due
to tone.
OR
If you know the tone freq, just notch it 6-8-10-15 dB - whatever you need.

I'm not sure why you say the DSP has to eliminate the tone. It could easily
be made to only reduce the tone to a a specified level.

I think the tone detector-PLL is not too good a method. Getting the phase
shift to do a cancell will take an adjustable all-pass phase shifter. Not
impossible, but complex as well.

Go to a new home site (under construction) and pick up a few inches of PVC 1/2 in. or 3/4 in. cut them to an appealing size and drill some holes in them at their ends and BAM, insulators!

I like mine professional looking so I buy them from Buxcomm.com. They are inexpensive and in several designs or styles and Buck got good prices too!!

Hi !

That transformer is working in saturation.
Maybe you can see a welded line in the iron going over the plates.
Maybe not. It depends on design

Saturation guarantees good enough regulation for magnetron HT.
Also so called line conditioners and AC stabilizers are working with
saturated core.

Saturated cores are getting warm even withouth any load.
Added load doesn't warm up them remarcable any more.

Maybe saturation is an advantage for you because of regulation phenomena.
Test regulation with variac in input but use some load in secondary !

Line conditioner behaves so that in certain lowered input voltage the
saturation stops and output trends to drop.
To guarantee stabilization and conditioning they need some load all the
time (5 % of max allowed power is normally OK)
Line conditioners are normally working in resonance principle.
Therefore they have a nice flywheel efect. Gaps or glitches in line
sinus form are removed

2611. New program - SKYTRIG

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-01 23:56:26 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <I8KdnSI2msqQP8vZRVny2Q@bt.com>
Source record: 12312

Program SKYTRIG - SKYWAVE TRIGONOMETRY

With an input of elevation angle, layer height and critical frequency,
the program calculates skywave path distance, groundpath distance,
spreading (dispersion) loss, field strength from a 100 watt
transmitter, and the MUF.

The program can be used for guidance on the low MUF's and the geometry
of near vertical incidence radio paths over short distance
groundpaths.

Elevation angle is NOT the angle at which an antenna radiates the
strongest signal. It is the angle of the path taken by the radio wave
between two places on the Earth's surface and is nothing to do with an
antenna.

The program notes provide some elementary information on the heights
and behaviour of the various ionospheric layers in sunlight and in
darkness. Also on factors which affect received field strength such as
operating frequency being greater than MUF.

Download in a few seconds program SKYTRIG from website below.
Filesize = 42 kilo-bytes. Run immediately. Or you can open/run it
without downloading.

The PLL can correct phase as well as frequency of the cancelling tone - it's
trivially easy.

==========
Suggest you don't make the enclosure too small for a matching box (tuner).
Any inductor too near metal , will affect the inductor's Q
A rule of thumb is to keep the inductor away from the enclosure not less
than 1 diameter(of the inductor)
For this reason I am constructing an antenna matching unit in a plywood
enclosure or perhaps MDF ,although I understand MDF is no longer used in
the USA,because in contains phenolic resin. Perhaps someone in the know
on this NG can confirm this.

Hi Frank,

It sounds like you are going to an extreme that will create as more problems than it solves.

There is very little Q change in an aircore inductor of typical form factors when it is brought near sheet metal unless that sheet metal is in the core axis within a core diameter or less. The reason for this is air does not saturate, and the magnetic flux simply moves to a better spot.

There are only two exceptions to the generally very small Q reduction by a coil being near metal. The first is when the inductor is operated very near self-resonance, at which point any stray capacitance can seriously affect coil Q. The second is when the metal totally encloses the inductor and is so close it reduces inductance a significant amount.

MFJ has that problem is some small tuners, where the end of a 2 or 3" diameter coil is mounted right up against the sheetmetal (nearly zero spacing) and the when the cover is installed the other end has metal a fraction of an inch away. Unloaded inductor Q drops about 45% from 220 to 120 in that tuner whe the full coil is being used, and it is an exceptionally bad layout. Had they stayed an inch or two away from the ends of the coil it would not be an issue.

When you place components in a "transparent" box, you now have significant new problems. You have no reliable groundplane. Wiring is

an issue. There also is no containment of fields, you have created a small antenna in the room.

Most of the problems in tuners are caused by the tuner not have enough capacitance or using an inductor with crappy Q to start with, not by the box. You have to work at it pretty hard to make a design where the box kills the Q, but it is easy to make a box that radiates harmful RF into the area around the tuner.

If the LOAD on teh device is too high, it is possible for the
"bottoming voltage" or anode voltage necessary to pull two times the
current through it to be more than doubled for double the current.
High plate resistance devices operated with too high a load will NOT
have a constant dynamic anode impedance with varying plate voltage.
This is because the instantanious voltage across the tank circuit
during conduction is the supply voltage minus the tube voltage drop.

If the tube drop is more than doubled when the current(and supply)
voltage are doubled, it means the voltage across the load is LESS THAN
doubled. The load being ohmic, this causes less than double the current
to flow, and cuases downward carrier shift.

No help, probably, but most early marine radars used the type diode you
are looking for, usually in a matched pair (one reverse polarity from the
other). A most common replacement, and which worked as well or better was
the 1N415E (or F too, if I remember correctly) The 415's cap could be
installed on either end for reversing the polarity.
Both the 23 and the 415 types are very sensitive to damage from
external RF fields and static electricity. Came packed in metal tubes, metal
foil or other RF protecting packaging. If your use is very critical, try to
avoid buying any not in original, unopened packaging.
But you probably already know all of that..... grin!

> Bob --
> Everything gets easier with practice, except getting up in the morning!

AMEN!

Bob,
The OP said a DSP was too complex, so I was keeping with that restriction (and assuming that he may have been an analog type of guy)
How do you propose to get the 180? An Exclusive OR type PD has *approx* 90 degrees for a type one loop and 90 should be possible with a type 2...so you need another 90. Not impossible by any means, of course. If the VCO is a state variable implementation or a phase shift type, you may be able to get another 90 degree section for "free".
The PLL lock time will allow a burst of tone at the start *and end*...(see next).
Then, when the loop is idling, with no tone to cancel you need a gating circuit to disable its tone from the output since ther'll be no tone to cancel and time for it to turn on/off. Sounds like a juggling exercise.
Comment?

The PLL lock time will allow a burst of tone where a notch/equalizer won't and it sure seems a notch is very simple - a hand full of parts in a twin "T" or possibly narrowing it up with a augmented twin-T (twin-T and amp)...or there may be another band reject, I think based on the Wein bridge or some other active filter topology.

Now that I think about it, I suspect there may me a way to just change where the tone in inserted into the path to eliminate it from the dispatcher's speaker/phones.. But that assumes access to the system and the OP may have just wanted to stick something in the output jack for the dispatcher...
There may even be a "dispatcher tone injection level adjustment." (:-)

Perhaps it is set too high now...

This is the type of problem that I *know* has a really simple solution.
It's just knowing all the constraints and getting the clue for that answer.

73, Steve, K9DCI.

Paul,

Welcome to the world of design...

No need to make a load to measure the ripple on the caps. You can
calculate it. I did this long ago for a 5V 28 amp supply I re-wound from a
28V 5A supply.

You have to know that for a capacitor, I = C * Dv / dt.

When the 60 HZ wave drops, the diodes drop out of conduction and the filter
cap is now supplying *all* the load current...and the voltage drops in the
usual capacitive nature following that formula.

I don't recall if you said the current, but...if you will be drawing, say 20
amps - you have the "I". If you have a "C" you plan to use from the old
design, you have "C". Dt is the discharge time between the (full-wave)
peaks from the bridge rectifier. This is 8.333 ms. minus the conduction
time. I forget the typical conduction time I have seen, but I'll assume 5
ms max-load (the diodes don't conduct very long, typically.and.and the peak
current is pretty high to boot!) -- leaving 3ms for the discharge time.
Then Dv is the ripple, or more accurately, the sag. Also, consider that the
peak voltage will be lower when loaded due to the transformer winding
resistance and diode drop and anything else in there.

So, solving for Dv. Dv = (I* dt) / C

If you wanted 20 amps and had 20,000 uF, You'd have (20*.005)/.02 or 3
volts of sag.

BUT! This assumes *normal* line voltage. If you DO measure as some of the
others suggest, remember that you'll be using whatever line voltage is at
the time. Consider when there is a brown out. Pick a low-line voltage, say
105 volts and use THAT voltage, Or the ratio 105/120 and adjust your output
voltage number accordingly when calculating things.

You have to make sure that *Everything* that you want to power from this voltage has enough voltage at the low point; series pass & Driver & driver's driver (perhaps the 723).

Finally, what I did to keep the required overhead to a minimum and, as a result, the dissipation in the series pass transistors lower (and guarantee poorer brown-out protection, unfortunately), I *added* a few extra, lighter gauge wire turns to the *OUTPUT* winding to supply the 723 and driver stuff. Add the same number of turns to each side of the secondary (put one and measure the volts-per-turn to figure out how many) and put a diode from both of them (pointing to) to another smaller filter cap. This requires, of course two more diodes and filter cap, but they're smaller. You also have to watch the ripple in the same way.

Hope this helps. Let me know @arrl.net

Hi gang,

Reading through the instructions for this VNA it mentions some
important accessories; power spitters, 6db attenuators, 50 ohm
terminations, opens, shorts and throughs. What exactly is a "through"?
And is it possible to make up accurate opens and shorts oneself that
are good enough for calibration purposes up to 1.3Ghz? Not talking
about any absolute standard here, like you'd get from HP themselves;
but just mid-tolerance stuff that'd be sufficient for reasonably
accurate amateur experiments?
Thanks,
p.

> terminations, opens, shorts and throughs. What exactly is a "through"?

Probably a matched connection from point A to point B. This is often used to provide a certain line length for purposes of equalizing a time delay. You'll see that on many directional coupler assemblies, like when you open the front pod of a HP4191A.

> And is it possible to make up accurate opens and shorts oneself that
> are good enough for calibration purposes up to 1.3Ghz? Not talking
> about any absolute standard here, like you'd get from HP themselves;
> but just mid-tolerance stuff that'd be sufficient for reasonably
> accurate amateur experiments?

For hobby use, probably. The lab analyzers come with a calibration kit. The 50ohm resistor is a barrel with a connector. The open is just that, a tube that looks like the innards of the connector have been scraped out. The short is a connector with a precision gold plate in there that guarantees a solid flat contact between center and rim. Believe it or not, the 50ohm resistor of mine is now about 52.5ohms. Couldn't believe it, considering the profit margins on that stuff.

For the terminator I suggest to look at chip resistors. What is most important is to keep all the contact surfaces clean.

It sounds like you are trying to describe over modulation?
Otherwise, if the tube is operated within the linear portion of the
plate curve, the current will double when the plate voltage doubles as
Tom described.

Decreasing the loading on the tube means that you must also decrease
the modulation applied.

I am trying to find a 10.400mhz crystal to replace the one in a Uniden scanner I have. I have tried all the usual places such as Digi-key, Mouser, etc. I don`t want to order from some place such as International crystal because they would probably want a fortune for it in small quantities. Any help would be greatly appreciated! Rob

I've had good luck ordering custom stuff from Cal Crystal Lab / Comclok -
they seem to be quite good about providing onesies and twosies to
individuals.

Their web site is www.calcrystal.com - they don't seem to have a
10.400 in stock at the moment but I'd encourage you to give them a
call and see what they can come up with.

Well, they are the one place you will get EXACTLY what you need. But they
will be slow, and they wiill be expensive, although probably not "a
fortune". For a scanner, it probably only needs to be in the neighborhood.
Have you thought of taking an old FT-243 and grinding it? Probably your
scanner has an HC-49 or something so you would have to cobble something
together, but if you can find something in the neighborhood you should be
able to move it a bit.

I'm not sure how much a "fortune" is to you :) but JAN Crystals would
probably run you $15-20 shipped.

Being a Uniden/scanner part maybe there would be better luck at just
finding an old junker scanner?

A through is a direct connection of the two test ports (cables). If
all devices under test (DUTs) were "insertable", i.e. had one male and
one female connector (or GR or 7mm sexless connectors) then the test
port cables could be joined directly, thus forming a through ("thru")

Unfortunately, a lot of DUTs have the same sex connector on both
sides, thus a calibration thru must be a double, same sex adapter
(barrel). Using such an adapter during calibration adds some
unavoidable length (and loss and mismatch) to the test path length.
One method of removing (some of) the effects of the barrel is to
replace it after calibration with a matched length male-female adapter
that remains in the test path.

Depends. For SMA stuff, an open and shorted connector wouldn't be too
bad. Type N is a little more problematic but probably doable for
moderately accurate measurements.

BTW, even HP (Agilent) doesn't offer "absolute" standards. :-;

If this is a newer multiple conversion scanner and if this is the 2nd LO crystal, you will want it to be on frequency.......otherwise, your receiver will be off frequency and you will have unsymmetrical adjacent channel selectivity. You want your high and low frequency passbands to be centered. 10.400MHz is an uncommon frequency to find in the "junk box" so you will probably need to order it from one of the crystal manufacturers. If you don't have an internal trimmer to warp the crystal on frequency (your scanner hopefully does), you will also need to know the load capacitance for the crystal when you order it.

You can make a very decent 50 ohm load using two 100 ohm 0805 SMT resistors and an SMA PC-mount jack. Cut the center pin of the jack down to a height about the same as the thickness of the resistors, and solder the two resistors diametrically opposite, one side to the shell and one to the sawn-off center pin. The ones I've made check out fine up to a couple GHz...as I recall, better than 30dB return loss out that far. I've found the 0805 resistors work slightly better than 0603s, but as they say, YMMV, and unfortunately you probably have no good way to check them.

You can make a decent open that's nominally the same electrical length as the load by sawing the center pin off flush with the dielectric, and a short by shorting the pin to the shell. Do it with a tiny disc of copper foil if possible--but in a pinch you can use multiple lengths of wire radially out from the center pin. All these things should have as close to ZERO lead length as possible. At 1GHz, 1 millimeter is a little over 1 degree of phase shift, with air dielectric, and more with Teflon or other dielectric.

You can make a two-way levelling splitter if you are really careful. For a two-way, it's an input port that connects to two 50 ohm resistors, one to each of the two output ports. One output port is normally used to drive the reference port of the VNA, and the effect similar to the virtual ground of an op amp: the input port level is know or controlled accurately, so it's a virtual zero-impedance point there. Through the 50 ohm resistor to the test port makes for a virtual 50 ohm source impedance. Again, keep lead lengths to zero, or make any leads look like 50 ohms.

You won't get any VNA cal kits from HP these days...

Could be helpful to look for an S-parameter test set or a reflection/transmission test set to go with your VNA. You can find them on ebay sometimes. They can make life a lot easier.

Cheers,
Tom

Ultimately, a clipper (with a low pass filter to get rid of much of the
nastiness) might solve the problem!

VNA cal kits maybe not from HP, but most certainly from Agilent.
I do like my N4431 electronic cal kit, no lead swapping and really
fast (once it has warmed up).

If you try ebay, be sure to check connector condition.

Overmodulation is by definition to condition where DOWNWARD modulation exceeds 100%. I was describing the effect of OVERLOADING a class C modulated stage. Trying to even approach 100% upward modulation with an overloaded or underdriven final will of course cause modulation to exceed 100% in the downward direction. This distortion of the modulation characteristic is carrier shift. Nonlinearity in a linear(AB1 amplifying AM) final would cause the same sort of problem.

I learned this the hard way, and found that designing the final for the intended PEP output (and with MOSFETs applying a little gate modulation or driver modulation along with the collector modulation)solves the problem.

Hi all,

I need help to trace the following information.
Probably Old Timers may remember Professor Fantasky, a
cartoon on an electronic company advertisement
published in Electronic Design and similar magazines
end of 60s and 70s.

I made my QSL card having Prof Fantasky cartoon on it
as clear rapresentation of my homebrewing activities.
Funny Radio with funny options and blowing up....

At that time I had my QSL in black and white ... now I
would like to reproduce it again but in color. I lost
my old magazines and I cannot trace any original color
advertisement.

You may look at my QSL card at www.qsl.net/i7swx in
the "my callsigns" subdirectory at I2SWX.

Thanks for your help

Mike
First, Have you upgraded Windows XP to Service Pack 2, by any chance? I'm getting programs that won't run reliably, or at all since I upgraded. See the note regarding SP2 on the AADE site for the Filter program.

Second, A workable solution for running DOS programs under XP is DOSBox, now at version 0.65. Wes, W7ZOI's programs, along with the legacy DOS programs on the RF Cafe site will run under DOSBox. The problem in those particular cases is that XP makes them run full screen, and you can't get screen captures of the results. With DOSBox, the programs run in a virtual DOS environment in a window, and you can get screen captures (alt-printscreen, and open up MSPaint or other graphics software and paste the clipboard into the new blank drawing that appears. As a virtual DOS environment, DOSBox does have "DOS" memory limits and speed issues. Reg's programs should run with no problem in DOSBox. See Wes's website at http://users.easystreet.com/w7zoi/ , and on the main page, scroll down to "Some Technical Notes". The problem and solution are described in detail there.

73,
Ted KX4OM

If you are running it from a shortcut, and it ran ok before - then try
running it from the program directory and or remake the shortcut. Sometimes
the shortcut can get hosed.

This problem also occurs with some EZNEC installations. (The installer uses some 16 bit code, although the program itself doesn't.) For the simplest solution that's likely to work, see the second item in the list at http://eznec.com/ez40faq.html.

2653. MA110 specs?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-04 21:04:28 UTC
From: Leif Holmgren <nobody@nowhere.com>
Message-ID: <445A6C5C.6010807@nowhere.com>
Source record: 12254

Hello!

I have been searching for a datasheet for a diode called MA110 for a few days without any luck. Dozens of dealers are offering to sell me anything from 1000 to six hundred thousands of them but noone has any kind of data sheet.

I need to replace a single burnt one so buying even 1000 would be quite an overkill.

Does anyone know what's so special with this one? It's used in the battery charger in a ICOM IC2-SET and as far as I can remember one of a few of it's kind in that rig. Would you say it can be replaced with just about any 1N4148 (or whatever it's surface mount variant is called) or are there some special parameters that I need to look for?

/Leif

You are talking about devices that do not follow square law rules. I specifically restricted my comments to low mu triodes that were set to switch properly.

ANY modulated stage on a DSB AM transmitter with carrier and 100% undistorted sine wave modulation has to produce four times the power on envelope peaks and reach zero output on negative peaks.

The original posted has a pair of tetrode, which are multiple gridded tubes. Multiple grid tubes require some portion of audio be applied to the screen, control grid, or driver in orrder to be linear. **This is because the screen has significant control of anode current.**

In a low-mu class C plate modulated triode, the anode power and output power follows square law rules virtually independent of loading. This is why low-mu triodes are the tube of choice in distortion critical AM transmitters. The major point of concern where a low-mu triode deep into class C is not linear is when cathode emission is all used up, but that would be a terrible way to run the tube. Life would be a bigger worry than linearity.

> High plate resistance devices operated with too high a load will NOT

> doubled. The load being ohmic, this causes less than double the current
> to flow, and cuases downward carrier shift.

What you are saying is the tube has a non-linear plate resistance with anode voltage changes. The reason for this is screen grid tubes, tubes that are not deep into class C, and devices like collector modulated transistors do not make good mixers.

What always must happen when devices with less than desirable characteristics are used is we have to linearize the response by applying audio to some other stage or element on that device.

It's indeed true you can have a poor system and fiddle with the loading and operating point to linearize modulation. That was actually what I

was pointing out, that his plate modulated tetrodes were probably not working correctly through some type of design shortfall.

If you have to fiddle with loading to linearize the modulation, the PA design isn't a good one for AM.

The data-sheet site I use (www.datasheetarchive.com) doesn't have a
sheet for this part, but indicates that possible substitutes are the
1SS332 and 1SS355. Both of these are "fast switching" diodes - the
former handles 40 volts reverse, the latter 80, and both seem to have
continuous/mean current limits of around 100 mA, with a reverse
recovery time of around 4 ns.

It looks to me as if a 1N4148 might be an acceptable substitute, as
these have similar or higher voltage and current limits, and an
equivalent reverse recovery time. I would not use a general-purpose
rectifier such as a 1N4002, as the slower recovery time of a
general-purpose PIN-structure rectifier might cause problems if the
circuit is actually switching at a high speed.

The Polyphaser wenbsite is the best reference site.

Be sure to install ground rods at the corners of your house and in between and bond to your existing electrical service ground rod and copper plumbing (if you have any). You cannot overdo the grounding and bonding.. and that is your cheapest first line of defense.

Polyphaser has the widest selection of devices and will have the models you need for the rotor, AC and DC circuits. You ar thinking well to consider those circuits as well as your RF cables. I am surprised in commercial installations to see all kinds of ancillary equipment that is unprotected and extending wires out to the rooftop or tower.

The polyphasers coaxial prptectors are pretty much standard fare for commercial use as they have low let-through energy due to a DC blocking capacitor in series with the equipment side. For my station which is VHF-Microwave, I need DC continuity for remote preamplifiers. So I bought Huber and Suhner models from Tessco. (about $83). If you are familiar with the model numbers, you will know they are nicer construction than Polyphaser and you can sometimes find good buys on E-Bay, but be careful not to buy the DC stub models which are designed specifically for PCS and Cellular frequencies. The ones you want are a bulkhead type with N connectors and replaceable gas cartridge for the power level and frequency range desired. I mounted mine on a 1/8 inch aluminum rack panel. If you do something similar you can mount as you described in a large NEMA type box. Where are you located ? If you need a large NEMA type box (undrilled) let me know, I bought it for similar purposes and ended up with the bulkhead inside the shack.

You might want to look into one of those public address feedback cancellors that uses automatic audio notches. they might have adjustment on the notch depth which might be what you need. Call an audio warehouse and ask questions..

2659. FME "paper clip" antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-05 11:08:26 UTC
From: Doug Goncz <DGoncz@aol.com>
Message-ID: <1146827306.144897.228940@u72g2000cwu.googlegroups.com>
Source record: 12260

Hello, my new group.

Let me know if I am on topic for this group, please. It seems like rrah has had some cellular posts. There didn't seem to be a NG for cell hacks. Homebrew is the thing.

My Cingular / Seimens SX66 (HTC Blue Angel) has an FME RF port on the back. I couldn't find an accesory antenna without a cable at Wilson, or anywhere else. I usually lay it down on its face to protect the touch screen while I am using it with the headphones. When it's in the sun, this keeps the screen from overheating.

It seems natural to insert the _right length_ of suitable gage piano wire into the FME port but somebody could get an RF burn that way. I got one off my Motorola Star TAC long ago. God, what a clunker.

I guess whatever surface the 'phone was lying on would be a ground plane. I wonder if a metal surface would produce better results than a wood surface. I think it would.

What length and gage of piano wire would work? That is, the gage would be a pin to fit the FME center conductor socket and the length would be determined by an equation involving the speed of light and a factor applicable to the particular antenna design.

First off, is this a port for the cell antenna or for the WiFi?

What's the shortest wire I can use? A quarter wave in the 1800-1980 MHz band would be shortest, wouldn't it?

Could I just dip the wire in some grip compound, the kind you would dip plier handles in?

Would it help to heat-shrink this thin wire?

Would heat shrink and grip dip be enough protection for a reasonable level of safety?

Looking forward to more bars and bits per second more often. (I use it as a wireless modem, too) Might be some fun.

The smallest antenna I found was a Wilson mini that magnet mounts to the roof of a car. Not so good since I don't drive, and travel very light on my bicycle and by bus.

I can see a bus driver coming back to my seat and saying "Would you please take your antenna off the side of my bus? Somebody's gonna get their eye poked out!"

Why not just go BUY an FME adapter connector to fit whatever antenna
your trying to use. You don't have to reinvent the world just to
get an adapter.......

They don't make the antenna I am trying to use.

Yes, I can install my bit of wire into an FME male connector, but why not just use a wire that's the same size as that FME connector's male pin?

Here's another idea. Why not make up a metal _stylus_ that fits the FME female connector on my SX66? Then, I'd always have my extra antenna handy. Hm. My stylus is 4 inches long.

3*10^8 m/sec / (1900 MHz) = about 6 inches.

Doug

Hi Fil,
I think that if you use a mixer or sampler as a detector then it may well be possible to make the receiver relatively insensitive to harmonics in the source signal but if you use untuned detectors then it would be more of a pain.

If you were able to do proper VNA type calibrations then you would not need such a good return loss bridge, cables, connectors etc. I wonder whether in this age of cheap computing power, the VNA might actually be easier to build, for a given level of directivity after calibration.

Good luck and let us know how you get on.
Chris

Message-ID: <UJydnVJ5B5oKaMHZRVnytQ@bt.com>
Source record: 12266

For either line-of-sight or multi-hop propagation through the
ionosphere -

- this apparently simple program computes path loss in dB between
transmitter and receiver, field strength at the receiving site, and
receiver S-meter readings. Transmitter power output can be varied
between 10 KW and 1 milliwatt.

It is educational for newcomers and of assistance to DX and
line-of-sight experimenters. It illustates how S-meters OUGHT to work.

Download program PROPGATE from website below in a few seconds and run
immediately. Its at the bottom of the list.

It may be similar to the built-in speech processor that they used in their DSB-100 transmitter back in the early 1960s. If so, that unit, as you describe it, was quite effective for its day.

I need several quadrature hybrids (i.e. a 90 degree two-way splitter) for use in portions of the 0.5 to 2.0 MHz band. This is for a low-power phasing scheme. Normally I would obtain them from some place like Mini-Circuit but some reason they only offer a 1.13 to 1.38 MHz model (PSCQ-2-1.25). Can anyone suggest a source of supply?

Suppose I could also build them but am not familiar with the construction techniques used at these low frequencies. Am more accustomed to stripline and microstrip at VHF and UHF. Any suggestions here would be appreciated. I am sure the techniques are well known and must be covered in some articles, books and/or web sites.

Hi Joerg,
Sorry for the delay in replying; I've been away in Europe for a few
days.
It's the same HP 8754A analyser that appears in another thread of mine
hereabouts (4-1300Mhz). Probably rather too old for commercial
development use nowadays, although I do know an RF developer in
Brighton who still rates his one very highly and uses it daily.
Best wishes, Paul.

The article you are looking for appeared in the Jan 1968 issue of QST
and was reprinted in the 1972 HB. Maybe somebody has the 1965-1969
set of QST view? I have a copy of the 1972 HB, but it is quite yellowed
and might not scan well. The schematic isn't going to do you much good
since this is mostly a 'plumbers' and 'metal-smithing' problem.
The article and the HB detail the cutting and bending of the metal
(probably copper or brass as this beast must be soldered together).
Also some springy finger stock is required to seal edges for rf and
to contact the tube surfaces. Teflon is used to insulate parts and
forms the dialectic for some capacitors. Mention is also made of
beryllium copper. Be careful there, this stuff is deadly!

oops. The article I mentioned was actually a PARALLEL
amplifier, your post mentioned push pull. The article
mentioned is for 1296mhz (not vhf) where these tubes
are usually used.

Okay, thanks all.
I've obtained proprietory 50 ohm loads and power splitters, so just need to sort out the throughs, shorts and opens. The obvious question now is: in respect of throughs and open and shorted terminations, is the coax length of these relevant? I envisage making up N-type connectors with say one inch long coax stubs for both open and short unless there's some problem with this. Is the electrical length of the coax relevant?
Thanks,
P.

Since this is a full wave rectifier if we had ideal diodes they would be
conducting all the time (IE: one SET of diodes if a bridge or one diode
if a "CT" type rectifier). Also we have a SINE wave output, but in a
FW the negative cycle is flipped up. So your formulas don't reflect the
varying duty cycle out of the rectifier (it's not ON 5 ms and off 3 ms, but
goes from 0 to full voltage following a sine function). I guess you can
use the RMS function to determine the "effective" on and off times, and
your guess is probably ballpark enough to be correct.

Well, yes, length is in general important in a vector network analyzer. Let's say you have port 1 of an S-parameter test set, or a reflection-transmission test set, accurately calibrated at its connector. What is S11 if you connect nothing there? What is S11 if you connect an inch of coax there? If you tell me it's different in the two cases (which you better!), then you should pay attention to the length of the line to the open or short.

Another way to look at it: on a Smith chart, where will your 50 ohm termination be? Where will a short be? Where will an open be? If the "short" and "open" are at different distances down a line from their connector, even if you calibrate so the "open" is where it should be on the reflection coefficient display (Smith chart display), where then _should_ the short be, if you don't have the line lengths exactly the same?

And while I'm asking questions, what happens if you put your 50 ohm load, made with really good 0.1% 0805 resistors, at the end of a section of 50 ohm line which is not actually 50 ohms, but is instead 55 ohms or 45 ohms? The impedance tolerance on typical coax is pretty poor. Beware. It's actually unlikely to be as good as a carefully made load as I've described before here. (It's a real pain in the rear trying to set up a system to test things like VNAs accurately and guarantee your calibrations because of stuff like this.)

Cheers,
Tom

I found regular plain old receiving tubes worked OK down to 18 volts on
the plates - didn't have any convenient way of getting 12 at the time
but I'll bet they would have worked.

Audio power amps had REALLY low output but if you're building a 1-tube
regen you're not driving a speaker anyway...

The range from .5 to 2 MHz is an extremely broad frequency range to get 90' using any sort of LC network. It is greater than an octave, and that is why it's a problem. Generally, most phase shifters cover less than 1 octave....

If you are thinking about shifting a Local oscillator signal, I'd recommend a digital approach.

If you multiply the LO by 4, you can then divide by 4 to get perfect 90' phase shift.

I think some early Motorola auto radios worked off DC directly and had tubes in the RF and transistor audio PA's. You might look for some vintage auto radio schematics for tube numbers. I thing the 12AX7 tube might be included.

I have a 22-year old Icom 02-AT that has worked reliably until now, when it ceased putting out any transmitter power whatsoever.

Shall I assume the obvious, that the final (amplifier) transistor has blown? (They're easy enough to replace in most radios.) Or is there something else that's known to fail in these (particular) radios that results in a loss of transmitter power?

And can anyone please tell me the part number of the power device used in the final amplifier? Thanx.

I am willing to use several hybrids to cover the band, if I must. But it would be helpful to use broadband hybrids so I don't need to use so many. I appreciate the reference to the QST article on hybrid construction. I will build one to see how much bandwidth I can get. Would like to find a construction technique which yields wider bandwidth tho. The PSCQ-2-32 from Mini-Circuits has a 3.2 to 32 MHz bandwidth! Wonder how they do it.

The LO technique is not applicable for my design but it is interesting. I will have to give it some thought to understand how it works.

one by one.
through is actually a piece of cable used to connect the two ports of the VNA, prion to making what we call 2 ports measuremets: gain or transmission response. it just lets you set you baseline and calibrate out the incosistencies of the measuring setup.
for a short use the connector of your choice, with a well made short on the back side. cut a small piece of copper or brass drill a hole for the pin and solder everything as close as possible to the connector's shell
for an open, use again a connector of your choice with the pin cut flush with the back of the shell and left open. I used these made out from SMA and TnC connectors up to 3 GHz and they were quite allright for all practical purposes. I had the HP units to compare and they wewren't far off.

Well, for that requirement, you need :

G.W. Horn, I4MK, "How to design Wide-Band RF Quadrature Network"
QEX, November 1982, pp5-9.
3-30 MHz quadrature networks designed by VE5FP/VK2BOX

Rick Campbell, KK7B has "SPRAT Technical cartoons #1 and #2" that have
details on single band hybrids, and the component values for them.

Does it still receive correctly?

What usually happens, is the synthesizer quits, and it stops sending,
or receiving.

The output transistor is a T05 (TO39) type package, and is soldered to the
metal frame that surrounds the radio. It is very special, in that the case
of the transistor is connected to the emitter. Most transistors in that
package have the case connected to the collector. This is done so that they
could run the emitter grounded (as is usual) and not need any insulated
heatsinking hardware.

The usual way of blowing the output transistor in an 02AT is to use a battery
pack that supplies more than 9v, or to try and power the rig directly from
your car battery. ISTR that a short on the antenna is a third way.

Hi all and thanks again for all the responses.

Well I had another 10 minutes to spare again today so took a different
secondary tapping to try to get more voltage headroom. Following that
tweak, I now have 25.5VDC available across the large electrolytics.
This is obviously plenty enough for 13.8VDC regulated; but is it now
too much to drop efficiently?
Thanks,
p.

It's more than ideal but there is no such thing as "too much" if you've got an adequate supply of heat sinks and circulating air :-).

Is 25.5VDC measured at your "full load" current or at "no load"? If that's what it is like under a typical load then you'll get about 50% efficiency from a linear supply.

A switching step-down converter is possible but if that were an option you wouldn't be where you are today.

The no-load voltage is irrelevant for power dissipation because with no current there's no heat.

Tim.

Okay. It's just that in an earlier post you asked, "What exactly is a
"through"?"

I said, among other things:

"A through is a direct connection of the two test ports (cables). If
all devices under test (DUTs) were "insertable", i.e. had one male and
one female connector (or GR or 7mm sexless connectors) then the test
port cables could be joined directly, thus forming a through ("thru")

Unfortunately, a lot of DUTs have the same sex connector on both
sides, thus a calibration thru must be a double, same sex adapter
(barrel). Using such an adapter during calibration adds some
unavoidable length (and loss and mismatch) to the test path length.
One method of removing (some of) the effects of the barrel is to
replace it after calibration with a matched length male-female adapter
that remains in the test path."

Now maybe I didn't make it clear enough, but if nothing else, I
inferred that extra length, even in an adapter, is a bad thing.

You then ask, "...The obvious question now is: in respect of throughs
and open and shorted terminations, is the coax length of these
relevant?..."

Sorry to have been short, but it appeared that you didn't read, or
believe anyway, my answer.

Unless you know otherwise, as you would with fully characterized
reference standards, the open-short-load-thru's are assumed to be
"perfect". A perfect short or open terminating a piece of coax,
regardless of length, is no longer "perfect". A non-zero length thru
isn't perfect either.

==========
25.5 V seems a normal voltage level for a regulated 13.8 V PSU , no way
too high.
Suggest you check the working voltage of the large elctrolytic
capacitors. They should be 40 V or higher.
I am currently repairing a Yaesu PSU ,output 13.8 V -20A max, having
40V electrol. caps in output of 25A bridge rectifier.
FYI the unit has a soft start facility being a 10 Ohms resistor in the
230V -AC supply circuit ; this to limit bridge rectifier inrush current,
charging the electrolytic caps from zero.
As soon as DC output (13.8V) is there, a relay will be energised ,its
contact shorting the above 10 Ohms resistor .

FYI,

The tubes designed to work on 12 v for the plate might be best, but there are a number of battery filament tubes that also migh give you some results. eg. 1L4,1T4,1U4,1R4,1R5, etc (all 7 pin miniatures). (there was a series of 8 pin octal tubes, too). Most of them ran filament voltages of 1.4 volts at 50 ma current. I built a audio oscilator with a 1T4 (pentode) as a kid and it would oscilate down to 7 volts on the plate!! Most of those tubes were designed for up to 90 v on the plate. Power audio tubes were like 3S4, 3Q4, 3A4, etc (which would run 3.0 v at 50 ma, or center taped filament at 1.4 v and 100 ma). The 3A4, pentode, as RF amplifier was good for something like 1/2 watt output or so, not bad for QRP and no transistors.

There was an older series of battery fillament tubes, designed for lead acid cells (all were 2.0 v on filaments and not much amperage, either). You'll have to consult an older tube manual for those if you want to try them.

hi,
I am working on an FPGA project.
It is a CDMA-based point-to-point communication system; two FPGAs each
works as a transceiver.
The final stage of the project is to send the data via the serial port
(RS-232) to an RF module.
Can any one support me a low-cost, serial (RS-232) Rf module capable of
managing data rates up to 1.25 Mb/s and working reliably within
buildings giving a suitable range (>10 meters).

I find that about 19 to 20 Volts off-load is about ideal for 13.8 Volts output - if your unregulated voltage is much higher than that, you make a /lot/ of heat! If you're using a suitably rated transformer (so that the secondary voltage doesn't dip too much under load), 19 Volts gives ample headroom.

A brief word of advice - if you're going to use a 723 type regulator (usually a good choice), be careful to RF-bypass the op-amp (inside the 723) and provide an over-voltage trip of some kind. It is sometimes possible for the 723 to suffer from "RF brain damage" and completely lose the plot if you get enough RF in the wrong places! The best over-voltage trip is really brutal - a high current thyristor to ground after a fuse in the unregulated DC rail driven by a simple transistor and zener comparator - if you get it right, you can get a large "thump" out of the blowing fuse!

Bob

Saying:
> Since this is a full wave rectifier if we had ideal diodes they would be
> conducting all the time (IE: one SET of diodes if a bridge or one diode
> if a "CT" type rectifier).

Ken,
This is true only without the capacitor filter. When you add a capacitor input filter, the diodes (ideal or not) only conduct for a rather short part of the input cycle. Line current is in the form of rather short current pulses as a result. This is a concern for the power company, by the way. It also keeps the power company wave form rather flattened on the top, because of all the supplies on the grid drawing current only there.

You can see and measure this on a supply if you have the capability. The cap will charge, pretty much to the peak. When the sine wave then drops rapidly toward zero, the caps "hold" that voltage and are now are supplying the load current. The voltage on the cap drops according to the formula. (the action of the regulator keeps the current at this point constant, so *THAT* formula applies)

> Also we have a SINE wave output,

Not once you add the capacitor input filter. You need the cap filter to (help) keep the output at the constant DC we desire.

> but in a FW the negative cycle is flipped up.

*** Yes and therefore you have 120, half cycles per second (in the US). That is 8.33 ms period (one peak every 8.33 ms). Draw a full wave rectified waveform, then plot some capacitor descharge on it and you will see that for a peak-to-peak ripple of, say, 10% the time the cap is charging

is rather short. This is the diode conduction time.

> So your formulas don't reflect the varying duty cycle out of the
rectifier (it's not ON 5 ms and off 3 ms,

I did mention that the diode conduction-angle duty-cycle does vary, but this is due to load current varrying - and it is predictable We only have 8.33 ms per pulse and the conduction angle is only 1-5 ms. depending on load. This *IS* the way linear supplies work. In theory and practice. That's why *that* formula works. If there was current in the diodes all the time, it would imply thta your capacitor filter ripple would be the full supply voltage.

> but goes from 0 to full voltage following a sine function).

Again, this is only without a capacitor input filter, if you refer to the output voltage.

> I guess you can
> use the RMS function to determine the "effective" on and off times, and

No, this does not apply to this situation. RMS refers to the effective voltage, not diode conduction times.
If you look at the *sine wave* waveform itself (full-wave rectified, in this case) then you can determine the charge and discharge waveforms and that is what I have described.
If you can get a scope and do some real measurements for yourself, you'll see I am correct. For light loads on the power supply, the diode current pulses are quite short ~~ 1 ms and go only to around 5 with a heavy load.

> your guess is probably ballpark enough to be correct.

No guess here. What I described *is* the way it works. We do it when designing linear supplies all the time. You can see it with a scope. There are drawings on the web to show you what I tried to describe in words.

I didn't read all of the following web pages, so one may be easier to understand than the others.

The first shows *JUST* the rect waveform of which you speak:
http://en.wikipedia.org/wiki/Rectifiers

However, the rest of these show a capacitor input filter and the resulting waveforms and conduction characteristics I described.

The following has a movie showing very well and slowly, how the "Smoothing" capacitor works: http://www.greenandwhite.net/~chbut/rectification.htm

Ignore all the formulas in the following and about 2/3 of the way down are waveforms:
http://www.visionics.ee/curriculum/Experiments/FW%20Rectifier/Full%20Wave%20Rectifier1.html

Perhaps a simpler explanation:
http://www.play-hookey.com/ac_theory/ps_filters.html

I applaud your desire to help Paul's understanding, but you missed here.
73, Steve, K9DCI

Yes sorry, Tim. I should have mentioned that the 25.5VDC is the
open-circuit voltage across the caps.
I assume this new drop is do-able because this PSU in its original
configuration provided 24VDC regulated from 40VDC unreg across the
caps. That seemed like a hell of a drop without generating heaps of
heat, but I freely admit my recollection of linear PSU design (like a
lot of other electronics-related stuff) is very, very hazy.

>
> Your thinking of #30, 31, 32 and 45.

Nah, don't have to go back that far. I got a RCA tube manual copyright
1960, and it shows, for example, 1D5-GP, 1G5-GT, 1D7-G, 1E7-GT, 1F4,
1F5-G, 1F6 as all 2.0 volt filament tubes, and most of them are octal
bases, and one or two are 5 or 6 pin non-octals. And, I also know there

were a couple numbers not made by RCA, but I spend most of my time with my nose in the RCA manual.

And, I'm having a lot of fun in my early retirement years building a whole (retro) tube station from partly the junkbox, partly surplus, partly new, partly Radio Shack parts. But, I didn't know too much about the 12 v plate tubes although I knew they existed. So, after this year's recent posts, I started looking up the 12??blah-blah numbers in that tube manual and there is a lot there. Now gotta decide if I want to go that route or stay with the 1L4, 1R5, 1U4, 1T4, etc., route or use 6.3 v fil-cathode tubes with 100-200 v on plate. Part of me likes the idea of octal tube bases because they are so much easier to put into and take out of sockets (because of the keyed pin). Couple times in my life I dinged up pins on miniature tubes because I didn't look carefully at the pins on the tubes and the holes on the socket to line them up. Seems neater to have the keyed post; just aim the center of the post for the big hole, and then spin it around till it pops in. :-)

1.4 v filament tubes wouldn't throw a lot of heat in the summer time, either. If I built both kinds of rigs/receivers, I guess I could use the "hot" rig in the winter as extra heat for the room. And, the "cool" rig in the summer. ;-)

Thanks for your comments, otherwise.

That is a fine piece of equipment and not so large as the usual ones
are. IIRC it weighs under 40lbs. The difference between the 8754 and a
3577 can mean the difference between back pain and no back pain.

With that high of a data rate, I wouldn't use RS232. You'd be
better off with V.35 or perhaps RS485.

Happy tweaking.

Pretty demanding requirement. RS-232 at 1.25 Mb/s? I thought RS-232 topped out at 115200 or 230400 bps? That's the max you'll see for commercial RS-232 RF Modems, e.g., http://www.maxstream.net/, and they list in the low $hundreds per end.

Another approach is to use a serial device server, http://www.neteon.net/cat.aspx?clvl=3&c1=1&c2=3&c3=13, connected to a Wi-Fi network. Similar caps on serial speed, although one model claims 921.6 kbps max, the SSE-100.

And--I had posted something similar about length being important--it was the posting to which you replied asking about if length was important. You really would get more respect if you looked a bit more carefully at the info already posted. It would be a lot better if you would ask specific questions about what was already posted. The specific paragraph from my earlier posting is quite clear about the effects of length being important:

"You can make a decent open that's nominally the same electrical length as the load by sawing the center pin off flush with the dielectric, and a short by shorting the pin to the shell. Do it with a tiny disc of copper foil if possible--but in a pinch you can use multiple lengths of wire radially out from the center pin. All these things should have as close to ZERO lead length as possible. At 1GHz, 1 millimeter is a little over 1 degree of phase shift, with air dielectric, and more with Teflon or other dielectric. "

I can understand Wes' frustrations.

Cheers,
Tom

SolderSmoke!
A SHOW FOR ELECTRONICS HOMEBREWERS!

http://www.ourmedia.org/node/219981

Topics discussed in SolderSmoke #21:

-- Mike's new 80 meter homebrew rig
-- PSK 80 Warbler
-- Balanced modulator's: K2's '602 circuit
-- Bill's direct conversion receiver -- sweet sound
-- Verticals, slinkies, Bill's London antenna woes
-- Barbados receivers
-- Voodoo and RF amplifier construction
-- Tiddly-Wiki, VMWare, AFUKnoppix
-- Low Pass Filters
-- Barcelona SolderSmoke video
-- Telescopes & First Light for QRP rigs
-- MAILBAG: Alan, W2AEW; Nigel, M0NDE

Listen at: http://www.ourmedia.org/node/219981
Background:
Tired of listening to Led Zepplin or NPR on your
I-Pod? Wouldn't you like to be able to carry with
you the kinds of ham radio conversations that you
listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in
London, England meet regularly on the ECHOLINK system
to discuss their homebrew radio projects. We are
making them available as PODCASTS.

You can subscribe to the program, have them downloaded
to your MP-3 player, and listen to them at your
convenience. To subscribe, just cut and paste this URL
into your I-poder (or similar) software. (There have
been some problems with this subscription URL.)

http://www.ourmedia.org/user/36170

If you don't have an MP3 player you can just go to the
site below and listen to the latest program (and
earlier editions) using the audio software on your
computer.

http://www.ourmedia.org/node/219981

Here's the homepage for our show. All our programs are available here. There is also a blog and links to some of the sites and documents we've been discussing: http://www.ourmedia.org/user/36170

We hope you enjoy the program. Please send us feedback.

Source record: 12168

Radra, unable to contact you off group.

GM. I realize my reference is getting pretty old and may be difficult to obtain. If you'd like a .PDF of I4MK's 3-30 MHz quadrature 1982 article, I could send it to you, although it's a fairly large file. Conversely, he's still up and about and seems to be good in the QRZ call book.

His article yields the equations for a hybrid for any frequency and should (I think) give you a single solution for your needs.

Regards
W4ZCB

Wow, three requirements "low-cost", "serial", and "data rates > 1.25
Mb/s via RF " that are all self-contradictory :-).

And the device already has CDMA hardware in it.

An ethernet terminal server (ala Lantronics) hooked to a
high-throughput WiFi system might begin to meet what you want, while
you won't get 1.25 Mb/s you might reliably get a tenth of that with
some latency.

I cannot guarantee anything about WiFi interacting with CDMA
performance and in fact I would be pleasantly surprised if there were
zero effect.

Why does the device need CDMA on one side *AND* improbably
high-bandwidth serial via wireless on the other?

Tim.

Me too! Maybe you could put it on the web, in case there's more lurker
interest?

Maybe the OP was thinking of the older IC-2A. One of the battery
packs for the 2A had a jack for connecting 12V to it, which allowed
you to run the radio off the battery while it was being charged.
Applying 12V directly to the radio (only possible by removing the
battery pack) would fry it.

The IC-02A could run off 12-15V directly through a jack in the top
plate.

At the risk of going off topic, I recall someone mentioning that the RS 2 meter portable had an issue almost the same. The jack at the top was "supposed" to be for "vehicular" power - but I heard horror stories of the radio suffering damage when used in just that fashion. IAnd I've seen first hand - a battery pack that got smoked using vehicular power. It almost caught the guy's car on fire since it was near "cloth". I haven't looked at either the radio or schematic for so long - I can't recall exactly what the make-up is. I have though - heard many tales of guys blowing out radios in a vehicle. Hell, our Fire Department Squad Truck radio went out twice in 3 months from similar issues. I'm not sure if they actually figured out the exact reason as yet - Motorola and the original installer were to look over the situation. Seems to me, we all need to take an extra step to prevent such things from happening, since we can't rely on the manufacturers to do so. Just my 2 cents.

OOPS! The 02AT is ok on 12V, the 2AT has a problem with above 9V.
Sorry for the confusion.

I had a 2AT battery pack catch fire when charging off of the car charger.
There was no fuse in the power cord, and a wire shorted inside the pack.
Poof! It ate the wires inside of the pack, and the power cord all the
way back to the lighter outlet. A fuse would have been a *really good thing*.

********** REPLY SEPARATOR **********

My first job right out of high school in 1959 was repairing car radios, just when the 12-volt anode tubes were coming out. On a whim, I replaced some of the 12-volt anode types with conventional tubes such as the 12AU6 and 12BA6 and to my surprise, they worked fairly well, but with slightly lower gain. (The pin connections were the same.)

BTW, the 12-volt anode types were notorious for developing microphonics. It was an interesting design, but as soon as good transistors became available, they became history.

In other words, don't be afraid to experiment.

> battery
> pack that supplies more than 9v, or to try and power the rig directly from
> your car battery. ISTR that a short on the antenna is a third way.

...the jack on the top's supposed to have an internal regulator, and I've used it in my truck on occasion since the radio was new with no negative consequences (not like the HTX-202, which was made by Maxon under license by Icom for Radio Schlock, and had issues with its external power-jack).

Maybe infrequent long-winded transmissions over the last 22 years is the culprit for the transmitter's untimely demise? (It's kept my hands warm in the cool outdoors more than once.) I've long since misplaced (or

lost) the original manual, which had a schematic.

If I crack it open, I should be able to measure the voltages on the device, itself to see if it's blown. Right now, the final seems like the prime suspect. Thanx...

...Dave, N6BHU

Yeah, I've had a few experiences myself, in years past that taught me
there's no such thing as too many fuses.

My glove-compartment has an assortment of fuses of varying vintages, all
acquired for that "rainy day" that some times never comes.

It would not surprise me much if the failures were due to a "load
dump" event.

If the alternator is running, and supplying a substantial amount of
current to a load (e.g. headlights), and the load is suddenly
disconnected (e.g. headlights turned off), it's not at all uncommon
for a very impressive voltage spike to be generated. This is due to
the same sort of inductive "kickback" which can occur when shutting
off the drive current to a motor or relay or solenoid.

My recollection is that the standard used in the automotive industry,
is that electronic devices on a "12-volt" automobile bus should be
designed to survive load-dump spikes of up to 50 volts. A radio
designed for 12 (or 13.8) volt operation, whose finals are fed
fairly directly from the battery supply, may work just fine if the
ignition is off, but could easily fail on its first load-dump event.

Some sort of fast-acting zener protection, followed by an RF choke,
would probably be a good idea when connecting such radios to an
automotive power system.

Unfortunately, a 50-volt load-dump spike could exceed the input-
to-output voltage-differential limit of common regulators such as an
LM317; hence, even if you're using a regulator of this sort to power a
radio intended for 9 volts, you'll probably need an upstream zener to
keep the regulator from popping.

Very (perhaps highly) plausible theory -- it's too bad that Icom didn't
learn from Motorola, and create an inexpensive (relatively to their
radio, anyway) vehicular charger for their radios (e.g. 'Convertacom'),
rather than a (potential) built-in self-destruct device.

Hi Dave,

The I was thinking of the 2AT when I penned my response. The 02AT
is quite different. The synthesizer is more integrated, and there
aren't nearly as many crystals as in the 2AT. I am not certain what
the 02AT did for a final.

Assuming it is the same as the 2AT, it is a fairly simple job. You do need a
high wattage soldering iron, so you can solder the transistor quickly.
You should be able to make a few measurements, and determine if the
final is popped.

Yup. I also had a 3A and had to be careful about that.

I know the Icom batteries I bought with and for the 02AT had a resetting
thermal fuse inside, wired in series with the pack. I used those batteries
with the 3AT; don't know if they originally had different batteries.

Yep, but that doesn't help much when the circuitry fails between the connector
and the thermal fuse. Besides, the thermal fuse would only open if the cells
in the pack got too hot... not the 24 gauge wire.

In desperation, I once wired the triode section of a 6U8 into an oscillator circuit that had been designed for one of those 12v space charge tubes. It worked that one time, anyway.

I was replacing a pair of "VHF Triode-Pentode" tubes by Sylvania (I don't remember the type number) in an FM to AM auto radio converter whose performance really sucked. The other three stages were fairly easily re-wired to work off an external 250v supply, but the oscillator didn't look promising. The effort was a success. I think I at least tripled the distance from the stations at which I could hear them.

********** REPLY SEPARATOR **********

That reminds me of a fun thing to do when you have too much time on
your hands. Design a tube type oscillator that will work on extremely
low plate voltage. How low can you go? 12 volts is easy. How about
three volts? Or one? Or less?

I'd be interested to hear.

hello,

My superhet receiver project is moving on. I have audio amp, BFO, DBM for BFO-IF mixing, MC1350 based IF amplifier, crystal filter, 2N3866 based IF preamp and homebrew diode-ring mixer in front of it.

Now I'm experimenting with VFO, which I choosed to be Hartley osc. As I understood my DBM needs +7dBm from VFO, which should be approx 1.5 volts peak-to-peak.

I assembled my VFO prototype and made some pictures of waveforms from several points in VFO. Please take a look at them at http://www.algonet.se/~adok/aadu/vfo/vfo.html

Here are questions I have, and I hope some clever guy can answer ;)

* why is signal at point 2 not perfect sinusoid as in point 1?
* what are those strange things at the bottom of sine in point3 (secondary winding of broadband transformer)
* why is waveform at point 4 totally messed up?
* am I correct that peak-to-peak voltage at point 4 (VFO output) (204 millivolts) is way too low to drive diode-ring mixer which is connected to VFO output?

what should I do to rise output level. maybe add turns to secondary winding of T1?

I'm very grateful for any ideas/comments.

You never get a sine wave at the input to a DBM, it gets clipped by the diodes. However, there does seem to be something wrong with your buffer as the signal at point 4 doesn't look right. Substitute a 51R resistor for the DBM and check the waveform across it, it should be a clean sine wave at about 1.5 V p-p.

It is a good idea to build a buffer amplifier after the vfo. If you get more than +7 dbm build a little attenuator between the amplifier and the mixer. That way you get the right amount of drive, a stable load for the vfo, a resistive load for the mixer.

If you want to spare the time, you can send me the vfo and I will look at it on a spectrum analyzer for you and also tell you accurate power level into 50 ohms. I am in NJ.

Source record: 12190

I suspect, without going through a thorough analysis, that the output transformer, T1, has a self-resonance at perhaps 4 times (or 6 times) the oscillation frequency. Does the waveform change noticably when you change the VFO frequency? In addition, the amplifier stages, Q2 and Q3, are most likely being driven too hard to maintain a sinewave at the output. One thing that can mess up the sinewave is too heavy a loading at the output.

You might like to get a Spice program (there's a free one on the Linear Technology web site, as "switcher cad" I think it is, that's very respectable and does full spice, not just switchers), and simulate your circuit. Substitute a sine generator input for your first stage. I would model the transformer first as just an inductor with some parallel stray capacitance, and the output load reflected through the turns ratio across the inductance...that is, 33 ohms * (20/5)^2 = 33*16 ohms.

By the way, one clue I have that the transformer has a significant self resonance is that the waveforms are so different as you move the scope probe around. The scope probe capacitance changes the resonance. It drops it to the lowest frequency when across the primary, and a higher frequency when across the secondary, and has least effect when isolated by the 51 ohm resistor. Also, I just noticed that your schematic is labelled "3MHz VFO" and you are apparently running it at 15+MHz. Your output transformer should perhaps be different for the rather much higher frequency. Is yours like the schematic, or different? And the 2N3904s may well be behaving a bit differently than they would at 3MHz, too. Their hfe (ac current gain) will be noticably less at the higher frequency. Also, your construction technique as shown in the pix will allow for lots of parasitic self-resonances up in the 100+ MHz region, and that could be contributing.

Hope one or more of those random thoughts hits the target...

Cheers,
Tom

What are Q2 and Q3 if not a buffer amplifier? Q1 is the VFO proper.
One would hope that Q2 and Q3 don't oscillate at all.

Harmonic distortion.

> * what are those strange things at the bottom of sine in point3
> (secondary winding of broadband transformer)

Bumps. As K7ITM pointed out your output transformer probably has a
self-resonance, which is excited by harmonics in the incoming signal.
You need a good wideband transformer there, or you need a tuned tank
circuit (which will help suppress those harmonics).

> * why is waveform at point 4 totally messed up?

I'll go with K7ITM's answer.

> * am I correct that peak-to-peak voltage at point 4 (VFO output) (204
> millivolts) is way too low to drive diode-ring mixer which is connected
> to VFO output?

Yes. You need an amplifier with approximately 50 ohms output impedance
that will put 1.4V on the diodes -- less than that and they just won't
turn on.
>
> what should I do to rise output level. maybe add turns to secondary
> winding of T1?
>
> I'm very grateful for any ideas/comments.
>

To raise output level I would work on your buffer/final amplifier.
These things always amplify less than one would want.

I would also change your VFO design a bit. I'd keep the output tap at the hot end of L1, but move the feedback tap to the source of Q1 up to 11 turns or so from the hot end -- the signal that Q1 sees is between it's gate and source, which is huge with your circuit.

Once you've done that you can get a lot more signal to Q2 by bypassing the 10K resistor with a cap. This will load your VFO more, but will get you more power out -- it's a tradeoff you'll have to make one way or another.

If it were me I'd bias Q2 and Q3 separately. The schematic you has saves a few resistors but it makes everything in your output circuit depend on everything else. If you separate your bias circuits then you can design Q2 to be the World's Best Buffer Amplifier then concentrate on making Q3 to be the World's Best Power Amplifier. Sticking a Q4 in there to get the gain up even more may not be a bad idea.

>
> * why is signal at point 2 not perfect sinusoid as in point 1?

First of all: at point 1 you're very close to a high-Q tuned circuit.
If you look at the gate of Q1 you will see an even more perfect
sinusoid.

At point 2: You seem to be clipping on the positive peaks. Shifting the
bias of Q2/Q3 let you at least somewhat equalize positive/negative
clipping. I think your Q2/Q3 was designed as a Darlington pair with
some degeneration BUT it looks like there is a poor choice of bias
point. Tweaking resistor values will give you good control over bias
(although if your rig has to run over a wide voltage range you probably
want a very different bias network.)

Suggestion at point 2: going to a push-pull pair will make the clipping
be more symmetrical (e.g. get rid of most of the 2nd harmonic).

At point 2 you're broadband so no high-Q tuned circuit to make things
look like nice fundamental sine waves anymore.

> * what are those strange things at the bottom of sine in point3
> (secondary winding of broadband transformer)

Point 3 is *roughly* an inverted version of what you have at point 2
(this is consistent with the phasing you indicate on the schematic.)
There's a little bit of ringing.

> * why is waveform at point 4 totally messed up?

I think point 4 would be the same as point 3 except for the 51 ohm
resistor in series, right? I think what you're seeing is capacitive
coupling of higher-frequency harmonics around the resistor. Essentially
the resistor/scope probe combination is making a high-pass filter that
makes the signal look worse. If anything, to make the signal look nicer
you want low-pass filtering.

> * am I correct that peak-to-peak voltage at point 4 (VFO output) (204
> millivolts) is way too low to drive diode-ring mixer which is connected
> to VFO output?

It's not ideal, but things will kinda-sorta work with poor performance.

> what should I do to rise output level. maybe add turns to secondary
> winding of T1?

I would change your buffer stages to a couple of class-A WELL-BIASED gain stages. Or go to push-pull. And then add some low-pass to only let the fundamental through.

A trivial example of a CMOS "push-pull" gain stage would be a 74HC04 powered by 5V for example, capacitively coupled into and with DC point set by a 100K etc. resistor from output to input. You'll get nice 5V rail-to-rail trapezoidal (almost square!) waves with this with an output impedance in the low hundreds of ohms. From this you do some low-pass filtering if you want it to look nice, but your mixer may indeed be happier with square waves, and you may indeed want to generate an 180-degree out of phase square wave.

Tim.

Okay, thanks for that clarification (likewise to others who've chipped in, too).
I'm building up a picture, but it's not so easy in this text-only medium.
Okay, so I think it's overwhelmingly clear that adding or subtracting any electrical length from this "baseline" - (or "reference plain" as I think it's also called) introduces measurement error which must be allowed for/accounted for in some way to maintain accuracy.

Let's say I make up a short and an open using N-type plugs as described elsewhere on this thread, using identical, high quality plugs. Can I then use these with my proprietory Suhner 50 Ohm precision N-type load by calibrating out any differences between the home-made jobs and the proprietory one?
Further, I now know that a "through" is simply that U-shaped patch lead that's often seen sticking out of the front of VNAs in catalogue pictures. I also know that you can't make one of these with zero coax length for obvious reasons. Given the fact then that it has an unavoidable length; does it have to be any *specific* length in relation to the open, short and 50 ohm terminations?
Thanks.

> lot of other electronics-related stuff) is very, very hazy.

A MUCH more relevant number would be the average DC voltage and minimum DC voltage across the caps under pretty much full load.

A good dummy load for an unregulated supply is auto bulbs/headlamps in series/parallel as appropriate.

The average DC voltage under full load is very relevant to overall heat dissipation.

The minimum DC voltage (that is, put it on a scope and observe the bottom of the ripple) under full load is very relevant to making sure you have enough headroom for your regulator.

If you don't have a scope you can guess what the ripple is from average DC and rectifier type (half or full wave). Guess won't be far off from reality unless you've got abysmal ESR caps or really really sucky transformer.

As to headroom: Typically for a high-current supply on a 723 chip, there would be a "secondary" supply at higher DC voltage that helped you develop drive to the pass transistor. Without this you need several extra volts headroom.

So far you haven't given us an awful lot to go on :-).

Tim.

2746. TS-940S Sub-Display Fades In and Out

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-10 17:34:15 UTC
From: KC2PIH@gmail.com
Message-ID: <1147282454.997353.45540@i40g2000cwc.googlegroups.com>
Source record: 12197

Hello! I have a 20 million serial# TS-940S (Mint!).
The Sub-Display currently has two problems - I think they are
unrelated - but this is a guess.

1. Ever since I had the radio (4 years ago), the LCD display fades in
and out. The actual black liquid crystal letters fade away almost
completely and then fade back in, randomly. Not related to activating
any function of the radio or temperature. Its almost the effect you
get when viewing the display from an off-angle how the characters
displayed tend to get dimmer. However - I am viewing it straight on
and it changes in intensity. I think there is a contrast adjustment
and its as if that is not holding its value. Need some advice on this
one. I am NOT referring to the light bulbs here - they are both fine
and hold a constant lux. The Kenwood "Erratic LCD" TSB doesn't seem to
fit my problem and I think my 20 million serial number isn't included.

2. The LCD display itself is now (recent) showing just "stars" (all
LCD blocks are lit). None of the display buttons change
what is displayed. I have read elsewhere that this could be from
the internal battery going dead.

I know I should replace the internal battery for starters, but I think
the
fading display is another issue that I would like to troubleshoot
before I order just a battery.

Any and all advice appreciated!

Depends on how much you are talking about. Man often only needs this
much precision ;-)

> Let's say I make up a short and an open using N-type plugs as described
> elsewhere on this thread, using identical, high quality plugs. Can I
> then use these with my proprietory Suhner 50 Ohm precision N-type load
> by calibrating out any differences between the home-made jobs and the
> proprietory one?

Let me describe what the three cal devices look like that came with our
HP4191A (after all, this is the stuff that Hewlett-Packard has deemed
acceptable):

The "Short" is a flat nut with a closed end. It puts a flat plate
directly across the face of the DUT connector. No length there.

The "Open" is a longer threaded tube with a hollow inside, about an inch
or so long and closed off at the far end.

The "50 Ohm" is something I wasn't able to open w/o special tools but
will some day. It looks like the resistor is about 1/2" to 3/4" up there
from the DUT connector surface, firmly encapsulated.

All gold-plated, of course.

> Further, I now know that a "through" is simply that U-shaped patch lead
> that's often seen sticking out of the front of VNAs in catalogue
> pictures. I also know that you can't make one of these with zero coax

> unavoidable length; does it have to be any *specific* length in
> relation to the open, short and 50 ohm terminations?

The HP4191A has that, too. It needs to match the length that makes the
DUT and ref path equal. The one on the HP4191A is about 1-1/2" for a
zero length on the DUT. In order for the analyzer to be useful in
settings where the DUT has to be a bit remote, like in a vacuum chamber,
you can remove a little face plate, remove the "through" and install
your own longer "through". It's made from rigid coax.

One is that to properly fuse it, you can't have an excessive in-russ, or
you'll need a really big fuse and it might be too big to protect the smoke
hinside.
Another is that you reqally don't want to pound either the diodes or the
filter caps if you don't have to.

Okay, thanks for that description. I'm pleased to hear your standards
are all different lengths to such a degree that it's apparent by visual
inspection. Hope for mine yet, then!
I guess I could check the accuracy of the short and open I fabricate by
reference to the known good 50 ohm standard? For example, say I begin
with the 50 ohm load and calibrate so I get a single spot dead in the
center of the screen.
If I then substitute the short and the open in turn I would expect to
see that spot shift to the far left then the far right edge of the
Smith chart overlay. If it doesn't do so and deviates to any extent
from these ideals across the whole frequency range, then I've screwed
up their construction. Does that make sense?

Okay Tim, thanks. I'm not short of test equipment; only the savvy to
use much of it. ;-)
Seriously, in this instance I can easily measure the ripple nadir under
full load - if I can source some headlamps from someplace. This may
take a few days so I'll report back in due course.

Also if a toroid mains transformer is used, the transformer start-up current can be huge for a large (say 1 kVA) transformer, which could harm the house wiring or burn the fuses in the main distribution panel.

Depending at what mains cycle phase angle the transformer was previously disconnected and on what phase angle it is reconnected to the mains, the start-up peak can be insignificant or the current can be huge, which is limited just by the copper resistance of the primary.

==========
When switching on an Astron 13.8 V - 50 Amperes PSU ,the surge current is that high that it (usually)trips the mains 'over-current breaker ' in the switchboard. I shall now include a soft start facility (resistor in 230V supply) which is by-passed as soon as DC output is established.

Talking about 'mains fuses' : In Britain and many other European countries most (modern) domestic supply boards no longer have traditional (melting) wire fuses but (resettable) fast acting 'over current' cut-out devices .
There are 100 Amperes wire fuses in each phase of the incoming supply cable ,but these can only be replaced by the electricity supply company ,since these fuses are each fitted inside a separate 'wired-lead-sealed' box.

BTW the over-current breakers are separate from earth leak detection cut-out devices ,officially called residual current detectors (RCDs).

This might be a good time to mention that light bulbs, which I've seen recommended here as a test load, have a resistance when cold that's only about a tenth their resistance when hot. So you'll get some pretty awesome current when you first connect one. A supply with foldback current limiting probably won't light one at all unless the voltage is raised slowly.

I have been searching for a Kenwood SO-1 temperature compensated crystal oscillator for the last 4 years. When I did find them (eBay), they went for a fortune because I must not be the only looking for one. I believe the SO-1 runs at 20Mhz...are there other units that could be substituted? I believe the Kenwood SO-2, with also runs at 20Mhz, is still available. Can the SO-2 be wired in place of the SO-1? Or is there more to it than that?

Thanks,
Scott, WU2X

That's a cool thing to know.

Hmmmm ...

Bobbie Barmore was discussing IOT power supplies and their crowbars on
the GowBugs list a few months back. Seems that the test to see if the
crowbar's good is pretty simple:

1) Turn everything off
2) Safety tag and padlock all the breakers and the START switch
3) Ground everything that even might think about biting
4) Put a piece of (?) 32-gauge wire between HV and ground.
5) Pull the shorting sticks, button everything up, unlock and
untag the breakers, untag the START switch
6) Make sure everyone's clear and safe
7) Push the START switch

The power supply's good for something like 700 mA at 35 KVDC, and it is
a _really_ bad idea to get across it if you might pass less than abount
700 mA. But the wire's good for more than 700 mA, and so will look like a
short to the PS.

If the wire melts, vaporizes, or explodes, then the crowbar circuit is bad.
It should be unaffected by the test. Put 35 KV across a piece of 32ga wire
without blowing it up.

Hydrogen thyratrons to dump the power, and fast-acting circuit breakers to
Shut Things Down NOW, appear to be the way to protect the wire from the PS.
Fascinating technology.

Perhaps check out http://www.icmfg.com/tcxofaqs.html and see if they
make a TXCO which is suitable, or can be adapted to work with the
supply voltages and output-signal requirements of whatever piece of
(Kenwood?) equipment you plan to use this with? They say that their
TXCOs are available at frequencies of up to 20 MHz, as standard items,
and that higher frequencies may be available.

There are probably other manufacturers of TXCOs that you could adapt.

Scott, the SO-2 runs at 10MHz, so it wouldn't be a substitute for the
SO-1 (if the SO-1 is 20MHz).

I thought the SO-2 was 20Mhz: See:

http://home.computer.net/~pritch/images/so2hole.jpg

That is the source of my SO-2 info. The Kenwood TS-940S service manual specifies the ocillating frequency of the the SO-1 as "20 Mhz".

35 KV at 700 ma? Exploding wires might not dump all the charge (what size capacitor?). Maybe need 2-3 dozen carbon resistors in series with a milliamp meter to monitor remaining voltage?

That's what was cool about choke-input filters. Hmmm, wonder if I have
a 100 mH, 100A choke in the junkbox...

ok,

I replaced my buffer stages with a single class-A stage (used the same 2N3904). I even used the same broadband transformer. Good looking 4v p-p sine appeared on secondary winding. After adding 6db attenuator I finally got my 1.5 volts p-p going towards diode-ring mixer..

thanks guys!

I can't really see why the original buffer didn't work properly, it's a
circuit from the Handbook which I've used without any problems. I think
I simulated it to make sure it's OK.

I usually try to make my buffer output impedance 50 ohms (which you should have from the attenuator assuming it's a 50 ohm attenuator), and about 2.5 volts p-p open circuit (when not connected to the mixer). This makes sure the mixer diodes get turned on good and hard. When connected to the mixer, you should see a squarish waveform, not just a slightly flattened sine wave.

Should I add a low pass chebyshev filter between VFO and mixer?
I mean - does it give real benefit (or only in theory)?

It looks like a degenerated darlington pair (with some "pull-down" to
help clear out base charge) to me. Lots of isolation between in and out
I'm sure, but really class C into a broadband transformer which means
you'll get lots of harmonics out.

Tim.

If the harmonics are coming in such that they make the LO injection look asymmetrical, then they could be bad and should be eliminated.

Harmonics that are fairly symmetrical (e.g. odd multiples of the fundamental) are not so bad.

Front end selectivity ahead of the mixer will matter some.

Any parasitic oscillations (e..g. things that look like spikes at certain points in the waveform possibly due to resonances/"ringing" in active or passive devices or parasitics) are very bad and can cause broadband noise that even your chebyshev low-pass will have a hard time removing. Making sure that all the buffers are firmly biased in class A will help make sure you don't have any parasitics to begin with. If you've got parasitics in your LO chain then no amount of filtering will help!

Tim.

It's an ordinary DC-coupled pair circuit, there shouldn't be any
distortion. I've used something similar as a microphone amplifier.

It may have been the intention for there to be little distortion but
the waveforms really make it look like it was being driven into cutoff
(the flat-topping at point 2).

Even though it was being driven into cutoff the amplitudes are still
small so something is out of whack with biasing. Maybe there was
supposed to be a blocking capacitor in series with the 10K on Q2's
base.

DX-302 REALISTIC SHORTWAVE RECEIVER..MANUFACTURED IN THE EARLY 1980'S..THE DX-302 SELECTIVITY SWITCH IS A TRUE IF FILTER WITH WIDE AND NARROW..WILL ALSO RUN ON BATTERY POWER..HAS A PRESELECTOR TUNE SWITCH..30 BANDS OF 1MHZ ON THE INNER TUNING DIAL..AND THE OUTER TUNING DIAL TUNES EVERY 1 KHZ...RECEIVES FROM 050 KHZ THROUGH 30 MHZ..HAS ATTEN SWITCH TO CUT DOWN STRONG SIGNALS..AND BFO PITCH FOR LSB/USB/CW...RF GAIN AND AF GAIN/POWER SWITCH..HEADPHONE JACK AND COAX AND SCREW TYPE ANTENNA CONNECTOR..THIS RECEIVER IS IN MINT LIKE NEW CONDITION.NO SCRATCHES OR OTHER PROBLEMS WITH IT. .READOUT IS BRIGHT RED AND ALL LIGHTS ARE IN WORKING ORDER AND DIALS TURN FREELY.

This is a communications receiver that covers 10kc - 30 mc in 1 mc bands. This radio is in MINT condition. Original knobs, crisp lettering, cabinet and front panel are excellent. Rear battery box is complete with battery tubes. Large red LED readout, wide and narrow selectivity, AM/SSB/CW capable and much more make this a fun receiver. Original cabinet paint is PERFECT.

I agree that the circuit as built exhibited class C behavior in the buffer. My guesstimate is like 40% of the cycle has conduction.

But the same identical circuit has been floating around for at least a decade and has supposedly been built into many many different varities of rigs with great success.

I'm wondering if one or more of the following is true:

1) For most applications it doesn't matter that the buffer is running class C
2) If the circuit's bias is insensitive to normal variations in real transistors
3) If "bad luck" out-of-nominal-tolerance transistors contribute to the particular example built and scoped out.

Leon said he simulated it (SPICE?) and it worked OK there but a single simulation using nominal transistor parameters is hardly enough to guarantee real-world bias being stable.

My reaction to finding the buffer only in conduction for less than half a cycle would've been similar to yours, Allison, with maybe more brute force and a little less finesse in trying different resistor values :-).

At one time I had several rack mount Kiethley's in the 600 series but
their imput impedance was extremely high. I don't remember the numbers
now but they were far higher than normal VTVMs. We workd with
resistances where a fingerprint on the tubes (they used pencil tubes)
could mess up the readings.

Scott -

As N5IW knows from practical experience -- the main problem with most of the
Kenwood radios (TS-940S and others) built during the late 1980's involved
poor solder technique (quality control during assembly) and possibly the
usage of sub-standard solders.
http://www.qsl.net/n5iw/ts940.html

A thorough re-work of the most accessible boards (those most suspect to
prior owner tampering, poking, wiggling, and plug/unplug) may yield the
greatest results. As you can imagine; this process takes some time.
In summary, N5IW's total repair work on his TS-940S involved:

Correcting and reassembling 2 completely disconnected plug bodies
12 to 14 visually obvious cold-solder connections (complete removal of solder and resolder with a quality US brand)
30 or so suspected bad connections on various plugs and components (resistors, capacitors, etc.).

The cure for these intermittent issues is the comprehensive and careful examination of the multitude of plug connectors and their solder points used heavily through-out the rigs. This requires modest electronic skills (soldering, and careful attention to detail - you must have good discriminating eyes) and can be completed by the most novice technicians or ham operators.

It definitely beats the heck out of that "genuine" Atwater-Kent breadboard radio with miniature tubes that was posted on eBay a few months ago. For one thing it has a speaker.

I can't read Japanese, and don't want to install one of those language programs, but it appears to be sold as just what it is -- a cute kit. For the tinkerer, it can make for a neat little radio that can be a conversation piece in the corner of any living room or office.

SolderSmoke!
A SHOW FOR ELECTRONICS HOMEBREWERS!

CHECK OUT BILL'S NEW WEB SITE:
http://www.gadgeteer.us
Please feel free to link, bookmark, and send feedback.

Topics discussed in SolderSmoke #22:

-- Mike's RF amplifier struggles
-- Good RF citizenship: Bill installs LP filter
-- Loads and power out in RF amps
-- Bill's amazing UK hamfest (rally) adventure.
-- Fun with lasers and UV
-- Doomed to build a Binaural receiver
-- Website update, Google and Amazon ads

Listen at:
http://www.ourmedia.org/node/223906

Background:
Tired of listening to Led Zepplin or NPR on your I-Pod? Wouldn't you like to be able to carry with you the kinds of ham radio conversations that you listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in London, England meet regularly on the ECHOLINK system to discuss their homebrew radio projects. We are making them available as PODCASTS.

NEW RSS FEED: You can subscribe to the program, have them downloaded to your MP-3 player, and listen to them at your convenience. To subscribe, just cut and paste this URL into your I-poder (or similar) software. We've been having trouble with our Ourmedia RSS feed, so Mike (software wizard that he is) has homebrewed his own RSS feed. In order to subscribe to SolderSmoke, point your podcast software to:

http://kl7r.ham-radio.ch/soldersmoke.rss

If you don't have an MP3 player you can just go to the site below and listen to the latest program (and earlier editions) using the audio software on your computer.

http://www.ourmedia.org/node/223906

Here's the homepage for our show. All our programs are available here. There is also a blog and links to some of the sites and documents we've been discussing: http://www.ourmedia.org/user/36170

We hope you enjoy the program. Please send us feedback.

73 from London
Bill M0HBR N2CQR CU2JL

You don't need to /install/ anything - "babelfish" just redirects the page you want translated to another web site that does the translation, then displays it in your browser just like any other web page. It's one of the most sophisticated web applications, but the translations (obviously) aren't perfect, and can sometimes be hilarious!

Dietary Fiber-challenged "Ron" will probably make his soup out of my shorts again but I homebrewed my own version of this set sans anything made of plastic or the weenie 20-25cm loop and phony horn. These sets are available on ebay and not so bad a bargain for a guy that wants to build a set but not go chasing around for individual components. You can find the schematic and details on other ebay listings. There's some yakk on ARF for those wanting to investigate deeper.
Its further evidence of my "blue butchering period" of fake tubes like the Radio LL :)
Its a cute little receiver - nothing to write home about and struggles to drive a horn, fake or otherwise, on anything but locals. Maybe over-represented in that regard. Toss the horn and use phones and its quite respectable for 'radio' person.
http://www.sparkbench.com/gekken/gekken.html
Its a clean sounding rig and shouldn't be any disappointment in its price class unless you compare it to an old plastic $5 clock radio. Its the kit that counts!

That's twice now you've posted that link.

I doesn't look anything at all like an Icom or Yaesu. And most certainly not like a Drake. If anything, it looks like an over priced midrange consumer radio from the 80s. Which it is.

MSRP was $800, Jeff. Around 350-400 shy of the SX-1980, which was still
in some stores when this came out. THAT was 270 wpc.

When did you buy a common 46 pound stereo?

They aren't exactly common anyway. LOLOL

Thanks for the babelfish link..thats pretty neat too.

Anyhow I just thought this kit is kinda neat...dont see something like this everyday...only things close usually have a cassette player or cd player jammed into them...and no tubes.... I bet it is all plastic too....the base, the horn everything...

150.00 USD on ebay ~:>....kinda steep..... if they were 30 bucks I'd buy one just to get an up close look at it.

The tube "strainer" that accompanys the kit was kinda funny....I guess thats something that got lost in translation.

2816. low pass filter between vfo and mixer

hi,

I have chosen the IF frequency to be 8mhz (since I have crystals for
that freq) in my superhet project. So, VFO frequencies should be:

band (mhz) VFO (mhz)
--- ---
1.8 9.8
3.5 11.5
7.0 15.0
14.0 6.0
21.0 13.0
28.0 20.0

Well..now here is a question: can I use single chebyshev low-pass
filter for all those frequencies? Or maybe it's better to use different
filters with different cut-off frequencies?

thanks!

These can be purchased directly from Gakken for about $100 with direct express shipping from JA. It is all plastic.

Scott-

You can probably find service manuals on the web for rigs that use each version. It should be possible to get an idea how the footprints compare, what voltages are used and how similar are the loads. It may be possible to find another company's TCXO that could be adapted, but it may be just as easy to adapt the SO-2.

Your best bet may be to contact Kenwood's engineering department. It is conceivable that the two might be the same, but the SO-2 has better specs. It is also possible that there is a version available from Kenwood parts, identical to the SO-1, but used in their commercial radios.

Incidentally, if you do find an SO-1, the label can be peeled back to reveal a trimmer capacitor behind a hole under the "e" in Kenwood. I adjusted mine so the 20 MHz WWV audio tone is the same on USB and LSB. It is also possible to setup A and B vfos for 19.999 MHz USB and 20.001 MHz LSB, and adjust the trimmer so the 1 KHz beat notes are the same. Either way, you need a "musical ear" to be sure the two tones are the same!

> 14.0 6.0
> 21.0 13.0
> 28.0 20.0

Hmm, did you check those frequencies for spurious responses? Low-side injection can be a real problem. Remember even if you have a very clean LO system the mixer itself has to be switching at the LO frequency and will generate some pretty significant harmonics.

With a 20 MHz VFO on 28 MHz, the second harmonic would be 40 and minus 8 would put a spur response at 32.

At 14.35 you'd have a third harmonic of 6.35*3=19.05 19.05-8=11.05

I guess you might be OK, but you should look at all of that and the bandwidth of the RF stages between the antenna and mixer.

Unless you are using a true multiplicative (four quadrant multiplier) as a mixer, i do not see why you would want to put a low pass filter between the VFO and the mixer.

However, if you are using some switching type double balanced mixer, such as diode ring or hard driven Gilbert cell (such as MC1496, NE602 etc.) mixer, these should be driven with a clean symmetric square wave to ensure accurate switching.

A symmetric square wave contains a rich series of odd harmonics that could mix with the signals in the antenna. With the VFO at 6 MHz and 8 MHz IF, the third LO harmonic would be at 18 MHz, forming spurious responses at 18+8=26 MHz and 18-8=10 MHz, the 5th harmonic would produce other spurious responses.

Since you are apparently not designing a general coverage receiver, but a ham band only receiver, IMHO, it is a much better idea to put the effort to build filters into the front end (e.g. band pass filters for each ham band or a constantly tunable filter) ahead of the mixer. In the example above, the 14,0-14,35 MHz front end band pass filter would strongly attenuate the spurious responses at 10 and 26 MHz. While there would still be mixing products with the harmonics of the local oscillator, with proper input filtering, the RF port of the mixer would only contain some thermal noise from the input stage(s), which at HF would not be an issue.

As others have pointed out, your VFO frequencies are quite high and would ruin the stability. Also running the VFO below the received

frequency can easily cause harmonics to fall on the RF passband or IF frequency.

For local oscillator frequency stability you might have to use the mixing method (band crystal +/- VFO) or the offset-PLL method (VCO-VFO) / divide-by-N and phase comparator. In both cases you should check that none of the auxiliary frequencies (band crystal, VFO, VCO, VCO-VFO difference, PLL reference crystal or PLL reference frequency) or their harmonics fall on the input frequency band or the IF frequency.

With a limited coverage receiver this should not be too hard to do. Put all the generated frequencies and their harmonics into a spreadsheet and check for several points on that band that all spurious signals are outside the ham band under investigation and that these frequencies do not come too close to the IF bandwidth.

Even if you do not currently plan to implement the WARC bands, it would be a good idea to include them in this spreadsheet analysis, in case you sometimes would want to implement them too.

I like the idea of having 5-5.5 mhz VFO (for all bands) mixed with band crystal.
Lets take 40m band as an example:

I still must provide 15mhz to mixer (15 LO - 7 RF = 8 IF). Right?!

Now - how to produce 15 mhz from 5 mhz VFO and band crystal osc?
Obviously I need to add another mixer and feed its input ports with 5 mhz from VFO and 10 mhz from crystal osc. This new mixer would have 15 and 5 mhz at its output. Right?

Now..how to block 5 mhz and let 15 mhz go through towards my existing RF/VFO mixer?

Obviously low-pass is not an option here..

thanks guys!

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday May 21st 2006
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and

Hiya,

I'm using an AD9951 based 0-180MHz DDS as signal generator fed into four (or if anyone want more) AD8343's mixers - connected as doublers. The sweep I get is supposedly 0-2.8G but I can only verify up to 2.5G.

the harmonics suppression in the AD8343's are roughly around 50 to 60 dB, absolutely good enough. You do need a couple of directional couplers (or bridges) as considerations need to be taken depending on the frequency. I use tweaked broadband RF transformers from Coilcratft as directional couplers. good for 1200MHz +. If you write the measuring SW yourself, you can add the needed calibration additions as well..

There are sourcecode for this available on the net with the AD8302 as a detector. You will have an absolute limit of 60dB dynamic range and abt 2.7GHz max... Good enough for me tho'...

Quick and dirty? Yes, but it's cheap, easy to build and do the job.

Cheers

Dan / M0DFI

I'm sorry to hear about it, but what does it have to do with
amateur radio and the design of related electronic accessories? (which
is what 'homebrew' means in this context).

2N3906 PNP TO92 Package - $4.00 for 50
The 2N3906 is a bulk transistor...meaning the part is not labeled.
They ship in a Zip Lock packet and the packet is clearly labeled.

IRF510 - MOSFET AMP TO220 - 4 for $5.00

Crystal Ladder Filters anyone?
3.575611 Mhz HC49 Crystals - 5 for $2.00
4.9152 Mhz HC49 Crystals - 10 for $3.00
9.830 Mhz Crystals (SS2 package) - 20 for $3.00
LM7805ACV 5v Positive Voltage Regulators (TO220) 5 for $2.00
LM386N-1 - Audio Amp 6 for $5.00

Sticky Back Rubber Feet for your projects, self adhesive - 8 to a strip - 2
Strips for $1.00

Panasonic Wall Warts - 12VDC, 500mA (center negative) $6.00 each
If you need center positiove, cut off the end and reverse it. I use these to

power my
rock mites, my TT2, and all of my homebrew test gear.

8pf NPO Ceramic 50 for $3.00
11pf NPO Ceramic 50 for $3.00
12pf NPO Ceramic 50 for $3.00
22pf Ceramic 50 for $3.00
470pf Ceramic 50 for $3.00
560pf Ceramic 50 for $3.00
.1 uF (104J) NPO Ceramic 50 for $3.00
.01uF (103K) Ceramic 50 for $3.00

SPECIAL PACK - 25 of each listed ceramic $10.00
200 parts total

Cash, check, paypal now accepted

Paypal to: orders@hamradparts.com

Add $3.00 shipping to any order under $50.00 unless you are ordering the
special Motorola PN2222 transistors.

I have a delay line from a Tektronix 7704 -- free if you will pay the postage (should fit into a USPS Flat Rate priority mail box). (the power supply in this thing was shot).

Jack

2837. Modulation Inductor?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-19 02:56:21 UTC
From: Tony Angerame <tangerame@earthlink.net>
Message-ID: <W8SdndNbbsVRrvDZRVn-rA@comcast.com>
Source record: 12138

I've acquired a high power 50 watts plus tube type hifi output transformer. I'd like to try modulating a pair of 6146's with a hifi amp. The circuits I see use a modulating inductor in series with the B+ to the final to keep single ended dc off the transformer secondary.

Here's the rub. Where do you find a 30-50 henry inductor for 800+ volts? I was thinking of checking out the secondary of a tv transformer? (Not many left used to be common whatever happened to those tv's).

Anyone have any ideas on winding one? Seems to me taking an old transformer apart and scramble winding as much wire as one can afford might do the trick?

Ideas?

Thanks,

Tony,

WA6LZH

I assume you are talking AM modulation and that you really want plate
modulation.

Otherwise you are discovering why screen modulation was so popular
with 6146 finals!

I suspect he is talking Heising modulation, which normally is used
with a single-ended Class A modulator whose plate is directly tied
to the PA plate (the choke is used to provide a high impedance to
the filter chokes. But, what I wonder, a 50 watt tube audio amp is
very substantial, and is probably running Class B P-P. I don't see
how Heising modulation would work in that application.

Tony

What you need to do is to find a universal modulation transformer and replace the audio output transformer used on the audio amplifier. That is the most practical solution to your quest.

Agreed, but the choke must be able to stand the high DC standing
current without going into saturation. Also, the choke method
somewhat limits the maximum modulation unless a few
additional steps are taken. I'd be leary about some of the
suggestions regarding the use of pwr. transformer windings
to accomplish the task.

A blast from the past: Oftentimes the voltage rating of chokes was more
a limitation of breakdown from conductor/windings to the core or case rather
than interwinding breakdown. So..... a quick method of cheating on the
rating was to mount the choke on standoff insulators or at least insulating
the choke from any metal in the chassis or frame of the RF or modulator
deck. Only thing then is to be sure to treat that choke core or case as if
it might be at high voltage potential......yikes!
Although Choke modulation (or Heising as one respondent mentioned) is
"high level" modulation if applied to the RF final plate/s, it takes a lot
of tinkering to achieve 100% modulation (balanced, above and below zero).
Almost always a compromise in Amateur gear, and some broadcast gear came
close, but at great expense.
Many will throw rocks at me for this, but "low level" modulation is a
huge waste of RF power, and in the good (?) old days, was just another
weakly modulated hetrodyne the howling AM section of the bands. OH, OUCH,
OWEE, HEY!
Old Chief Lynn W7LTQ

Buying a copy of "Experimental Methods in RF Design" (the successor
text to "Solid-State Design for the Radio Amateur") would be a very
good place to start reading. These guys have written down a vast
amount of very practical information and experience about how to do
this sort of thing well and reliably.

http://www.bright.net/~kanga/kanga/KK7B/uvfo.htm is a "universal" VFO
kit which you might be able to adapt for your needs.

Doug Demaw W1FB had another "universal VFO" design in his "QRP
Notebook" (a great book if you can find a copy). You can buy a kit
for it (board, semiconductors, air-variable cap, copy of the
construction article) for $30 from

http://www.danscloseoutsandspecialdeals.com/kitcloseouts.html

I've bought stuff from Dan a couple of times and have always been
satisfied with what I've received.

Source record: 12053

Hello,

I'm building the "FARA"amplifier (QST June 2003).
Unfortunately, I 'm not able to get the T-3/4 cores, so I wonder whether I couldn't take two ferrite cores used to avoid the RFI made by the wiring of computers ?
Obviously, I will try it but I would like to get some advices before...

Here's a direct conversion transceiver that might give you some ideas

http://www.intio.or.jp/jf10zl/3trcw.htm

I don't think you will find that this is a particularly good receiver,
but it is the only IC-free DC receiver I know of on the web (and its
VERY clever!).

Or, if you have a circuit that uses a CA3028 mixer, you can easily make
up the equivalent from 3 NPN transistors and some resistors.

My 1933 ARRL Handbook does not have a schematic for a 5 to 5.5MHz VFO,
much less a solid state one.

Receivers that used 5MHz VFOs didn't start appearing until the mid '50s
(judging from my meager collection of handbooks -- I only have eight
spanning '33 to '76), with VFO SSB transmitters appearing about the same
time.

Someone who was actually alive at the time, or with a more extensive
collection, may be able to contribute more.

>Does anyone have any schematic for Direct Conversion receiver that does not
>use any FETs, Valves or ICs (e.g. NE602) but uses NPN transistors?

"Experimental Methods in RF design", section 1.8, page 1.13, has the
schematic for a DC receiver which uses NPN transistors throughout most
of its design (including the product detector). Tuning is done via a
varactor-based VCO - you might be able to substitute a reverse-biased
junction in an NPN transistor for the varactor.

There are two ICs - an LM7805 voltage regulator (for which you could
probably substitute a shunt regulator such as a zener diode or an NPN
transistor wired up as a Vbe-multiplier) and an LM386 audio amplifier
(for which you could substitute the discrete-NPN audio amp design on
the previous page of the book).

I'd say there's a good chance you could modify this design so that
every single semiconductor in it was an NPN transistor such as a
2N3904 or 2N2222 or a similar jellybean.

-- or for the shunt regulator you could use a back-biased base-emitter
junction in a 2N2222. It trashes the transistor, but it makes an
adequate zener.

> time.
>
I'm sure that was exageration, but they do have a point. 5MHz VFOs have
to be one of the more common items in the magazines and books over the years.
Even before 5MHz came along for use with a 9MHz IF, the books and magazines
were full of VFOs that could be shifted to 5MHz. There was a period when
6MHz was a common VFO frequency, for use with multiplying VHF transmitters,
and those would be even easier to shift to 5MHz than a 3.5 or 7Mhz VFO.

If someone is asking about a 5MHz VFO, they've not looked far. Now,
the case may be that they are looking for something more specific, but
in that case it makes sense to be specific.

If someone wants out of the book, yes they won't find a 5MHz vfo in the
1933 Handbook. But, once they go that far back not only will they be
tubes, but stability will likely be an issue. 1933 either predates the
laws requiring "crystal-like" stability, or such laws were recently passed.
Look at the diagrams from that era, and a lot of later concerns in
construction haven't come into common place.

If my memory is correct, the PSK-20 is used for, well... PSK.

That being the case, I think you might find it difficult to get adequate frequency stability using a free-running VFO. Since the PSK decoder software automatically gives you about 2KHz of tuning in software, a PLL approach would be quite easy and should produce a clean spectrum if done properly. I think a DDS solution would also be quite good for this application

There was an article in QST many years ago (late 1960's ??) which was one of the early direct conversion articles. This one used 88 mH filters, and a three transistor audio amplifier. It was written by Doug Demaw, if memory serves, and it is probably the simplest, but useful, direct conversion design I have ever seen.

Granted, getting 88 mH coils is not as easy as it was back then, but all in all, I think this fits the original request. The radio used NPN transistors thoughout.

But one thing about direct conversion receivers is that it took years before
they became good.

The basic premise, beating a signal directly down to audio, is as old as
the regenerative receiver. ANd of course there were explicit mixer/oscillator
type receivers in the decades after that, that all seemed to end in "dyne".

IN 1961, QST ran an article, I can't remember if it mentioned "direct
conversion", that was direct conversion as we came to know it. A mixer
and an oscillator, and if I'm remembering they used two tubes in the mixer
for a balanced mixer.

Then there's the Hayward article, there was a co-author, in 1968, that
actually did make mention of "direct conversion". It used schottkey
diodes in a balanced mixer. And that's when they took off.

But in the articles afterwards used just about any possible mixer,
with varying results. Everyone was trying to get a good direct conversion
receiver, but I'm not sure they really understood them. So the focus
was on another variation of a well-balanced mixer.

It took till 1980, before there was a real change. That's when Roy
Lewallen came out with his "optimized QRP transceiver", which featured
a terminated mixer. I'm pretty certain that's the first time a DC
receiver had a terminated mixer. I can remember the 1974 QST article when
terminated mixers for VHF converters were introduced to the amateur world.

I really do say that 1980 article of Roy's was the dividing line. Before
that, no matter how good the mixer there always seemed to be problems. Then
we moved into an area where simplicity wasn't the first consideration for
direct conversion, but performance came first.

The VFO used in the "Progressive Communications Receiver" by W7XZOI &
K5IRK, (QST 11/81; various ARRL Handbooks inc. 1990) is a good stable
general purpose JFET Hartley circuit VFO. It can be built to cover
frequencies from 2.5 to 10 Mhz. range.
The article has charts and calculations to derive component values for
the tuning capacitor, and inductor, etc. I've built one to cover exact
range you desire. As long as one follows good design practices, such
as: use NP0 capacitors only; tuned circuit should be lightly
coupled to the FET - i.e. use a small value like 2-3 pF cap., air
variable or small ceramic; the VFO will be stable. Power output is
around +5 to +8 dBm into 50 ohms depending upon type of dual gate
MOSFET used for the buffer amp.

Tony,

I did exactly what you are describing. I used a solid state audio amp, and drove a tube type audio output transformer backwards to step up the impedance from 8 ohms to several thousand ohms. I used a 4 uf oil capacitor to couple that across a HV choke that carried the RF final amp plate current. For a choke I used a 125 watt Stancor poly-pedance modulation transformer where I used as much winding on the primary as available. It worked very well.

It might be easier to consider cathode modulation, and in this case the transformer turns ratio will be much less, and the HV problem will also be less. Maybe a 110/220 vac to 12vac 5 amp filament transformer will work out here. This is just a guess, but it might work. Cathode modulation is a combination of plate and grid 1 modulation, so the % eff is somewhere between 66% (plate) down to 33% (grid) , and might end up at about 50%. Consider the 220 vct winding where the grid return goes to the CT, and the cathode goes to the top of the 220 v winding, and the bottom of the winding goes to ground. Your turns ratio need may vary, but the concept proposed is workable.

The direct conversion transceiver is what gave TenTec their start.
They had a few different models in kit, semi-kit, and assembled
formats. QST picked up the craze and there were a number of articles
on building these. Detectors were dual gate fets, CA2028's,
diode bridges, Mini-Circuit mixer modules, and later IC's with
built in vfo's.

Back in the 60's, there was an early direct conversion receiver that
used two 6SB7Y's in a balanced circuit with a B&W phase splitter run
bass-ackwards and an rf phase splitter in the vfo. This was actually
a single signal receiver using the idea of a phasing sideband modulator
in reverse. Today we'd call it an image-reject mixer.

What's old is new again.....

Usually, the ferrite cores used for RFI rejection are made of the
same stuff as those used in broadband power transformers so it
might work. However those cores are split in two for easy
application. Glue them together first with a good grade of epoxy
keeping the glue layer as thin as possible. The power handling
may not be as good as the real McCoy though.....

It looks like AM is really becoming a "lost art". Of all the responses
here, only one or two guy knows what you are talking about.

The purpose of the choke inductor like you are describing is to keep
the DC off the secondary of the modulation transformer. This allows
the use of a modulation transformer with much less iron, which will
give better low frequency response. If the finals DC current is run
through the modulation transformer, as is commonly done, there needs
to be an air gap in the transformer to keep the core from saturating
from the DC current. The bigger the air gap the less inductance, the
greater amount of DC current it can handle before saturation and the
poorer low frequency response. To increase the inductance with a
larger air gap requires more iron (larger core) to bring the
inductance back up.

By using a choke and capacitivly coupling the audio from the
modulation transformer to the final plate there is no DC on the
secondary of the modulation transformer to cause saturation. The
modulation transformer then can be any audio transformer. It doesn't

need an air gap. The transformer can have much less iron in it for the same amount of inductance as one with an air gap. Very good low frequency response can be had this way.

By the way the screens of the final tubes need to be modulated along with the plates too. The easy way is to supply the screens through a dropping resistor from the top of the choke, the same point that feeds the plates.

THIS IS NOT HEISING MODULATION. It is regular old plate modulation just like you would do with a conventional modulation transformer.

Yes power transformers can be used quite successfully as a modulation transformer with this type of setup even though there is no air gap in the transformer. There is no worry about core saturation because there is no DC current on the transformer.

A large enough choke for this application can be had by putting several chokes in series to obtain the required inductance. Regular power supply chokes work fine. Do not use a swinging choke! It has no air gap and will saturate.

A TV transformer will not work well as a choke because it has no air gap and the core will saturate quickly with DC going through it.

Cathode modulation is very similar to grid modulation in performance. After all audio is placed between the grid and cathode just the same as it is with conventional grid modulation. The amount of cathode to plate modulation is minimal.

Screen modulation is similar in performance to grid modulation also. Efficiency is around 35% carrier efficiency. Very tricky to tune up properly.

Low level modulation with a linear amplifier behind the modulated driver also has an efficiency of around 35%. Excellent AM can be generated this way as is done with some SSB transmitters in the AM mode. If properly set up one can not tell the difference between it and a high level plate modulated transmitter except that the plate modulated transmitter will probably have higher distortion.

>

I remember that one !! Seems to me, it was in Single Sideband for the
Radio Amateur and I was really tempted to try to build one.

Actually, I was responding to the original request for a direct conversion
using NPN transistors. There are a lot of designs for direct conversion
rigs, and some of them are excellent.

Personally, I like the designs by KK7B and if someone wants to try their
hand at it, the Kanga website has some kits available.

http://www.bright.net/~kanga/kanga/KK7B/minir2.htm

They also carry the R2PRO which has excellent characteristics

http://www.bright.net/~kanga/kanga/KK7B/r2pro.htm

I've homebrewed from scratch some direct conversion breadboards over the
years, but these are image reject and would be a good starting point for a
complete transceiver.

hi guys,

After an hour or more of pushing and twiddling various buttons and knobs on my VNA I have at least established two standards: I connect a short and the (polar) spot flys off to the extreme left-hand-side and sits stably on the central horizontal axis. I then remove the short and replace it with an open and the spot jumps across 180 degrees to the extreme right-hand side on the same plane. All well and good so far. Next, I replace the open with a lab-grade 50 ohm termination and I wind up with an arc on the outermost circle of the polar chart at about two-thirds of the way round the circumference (clockwise) from "12 o'clock" as opposed to a spot in the dead center of the display as I would expect. What have I done wrong? I have checked this with 3 different 50 ohm loads and they all show an arc at the 'south west' corner of the chart. What's goin' on here, guys??

You haven't fully described your setup, so it's hard to tell. What are you using for a bridge? If I recall correctly, your VNA is an HP8754A, which won't do S-parameter measurements by itself; it requires an external bridge (an S-parameter test set, or a reflection-transmission test set, for example).

The fact that you see an arc on the outermost circle, assuming that you have it set as a unit circle on the linear reflection coefficient plane (the Smith Chart outer circle), implies that you have a (nearly) unity reflection coefficient. Is something almost disconnected so it looks like a tiny series capacitance?

Oh, my gosh, you're right, Gary! It is not Heising modulation. For 60 years now I've had the mistaken impression that "Heising" implied simply that a series choke was used in the plate/screen supply to allow ANY modulation to be applied, either by modulator tube directly, or through a suitable capacitor.
I am embarrased. "Googling" brought up a whole lot of other aspects of high level modulation that I didn't know (or hopefully just forgot!)
Does anyone remember negative peak clipping that was the rage about 1958 or so? (Amateur only, as far as I know)..... If the scope wasn't lying, one of my home brew "high level" AM rigs was capable of modulation of over 100%. There was an awful lot of controvery at the time, and our nearest FCC chief engineer said that he didn't care if it did, it was still illegal.
Sigh.

Okay, thanks. I must admit it is symptomatic of the load's center pin
not quite making contact for some reason, even though the load is fully
screwed home. But the same thing happens with 3 different loads!
I'm using the T/R test set, by the way, although I don't see how that
could explain the problem. I don't have the full S-parameter bridge but
am in the market for one.

If you're using N connectors, check the center pins of the females.
Make sure that they aren't splayed open.

The local repeater association I'm a part of has had repeated problems
with splayed N connectors. They can be caused by a couple of
problems. A botched install of an N male can cause its center pin to
project too far forwards, out of the shell. We've also seen some N
adapters (Chinese-made I believe) whose center pin was larger than
usual in diameter, or was not tapered in the usual way.

In either case, if you screw an N male connector with a bad center pin
into an N female, the male's pin can force the split segments of the
center female pin outwards. Once this happens, a _good_ N male
connector's pin may not make reliable contact with the female's
damaged center pin. Intermittent nastiness can occur.

It's sometimes possible to bend the female's split pin sections back
together with needle-nose pliers, creating a repair which may or may
not be permanent. A better solution is to replace the damaged female
connectors entirely, and inspect all N male plugs and discard any
whose center pins are too large in diameter, not tapered properly, or
project too far out of the shell.

I suppose that similar problems might occur on BNC or SMA connectors
as well, for related reasons.

Low level modulation is a huge waste of RF power?? Hey, _AM_ is a huge waste of RF power, and of spectrum to boot! Except with unusual modulating waveforms, >2/3 of the power is in a useless carrier. Now, compared with plate modulation of the PA, low level AM modulation followed by a linear amp may be somewhat less efficient (though a waste of DC power, not RF power), but remember, the modulator, presumably being a linear audio amplifier, isn't all that efficient either. In addition, there ARE ways to generate AM with low level modulation and efficient RF amplification--they have been used in AM broadcast transmitters.

For the cost of a good high-level modulator, how many kilowatt-hours can you buy?

Cheers,
Tom

Looking at your web site I see you seem to manufacture CB amplifiers?
I also see you fail to post the 3rd and 5th order intermodulation
performance info. They must be pretty bad.
Also no low pass filter to attenuate the harmonics. -30 db second and
third harmonics are unacceptable. And those are at below power spec
on the amplifier.

How do you measure peak envelope power?
Where do you come up with PEP at 3 times carrier power?
What makes you think that PEP is going to be any greater than the CW
power output capability of the amplifier?

Hello Chief Lynn,

You are a couple of years ahead of me. I didn't get started until
around 1960.
I built a small modulator a few years ago and played around with
negative peak clipping. Never could get it to sound good though.
It will allow higher positive peak modulation without over modulating
in the negative direction but the clipping on the negative side
created a lot of distortion.

Broadcast stations regularly run around 120% positive peaks and near 100% negative but they usually do it with clipping at low levels and clean things up after the clipping.

I remember hearing about the FCC being in a quandary about some of the super modulation schemes like the Taylor system that could create upwards of 150% or greater positive modulation.

The only modulation method that I've ever found to be of any real efficiency in generating AM is "outphasing" or "ampliphase". You can use the /most/ effective PA designs - optimised FET-based Class E stages can be over 90% efficient! This approach completely obviates all the problems with modulation transformers or big chokes. Haven't tried it with valves ("tubes" - US) - perhaps that should be a future project.

Correct, and the distortion can be pretty nasty, too.

> Screen modulation is similar in performance to grid modulation also.
> Efficiency is around 35% carrier efficiency. Very tricky to tune up
> properly.

It was the /only/ type of AM I used at first, as I was unable to get big mod transformers. It worked well enough, though it was difficult to get close to 100% mod. Lots of envelope feedback cured the non-linearity distortions.

Low-level mod with a linear is very inefficient (with respect to DC input), but is sometimes the only really practical way to proceed. Again, lots of envelope feedback can sort out the distortions caused by less than perfect PAs!

Plate modulated transmitters are not all that low distortion in
general. It is much easier to get a very clean low distortion AM
signal by doing it at low levels and amplifying with a linear amp,
provided the amplifier is run properly.
At low levels modulation can be done with class A modulation stages as
opposed to typical class B high level modulators and non linear
modulation transformers.

Even with 33% carrier efficiency of the linear amp the total amount of
AC power required from the power company isn't much different. With

the linear amp there are no large modulator tube filaments to light, screen, bias and plate supplies to run the modulator.

With the new FCC rules limiting the peak envelope power to 1500 watts it makes more sense to use low level modulation and an amplifier than it did with the old rules. Now plate efficiency does not matter, you can still put the same amount of power into the antenna no matter what the efficiency of the transmitter is. In the past you wanted the highest plate efficiency that you could muster to get the most power into the antenna.

I believe that the thinking of the past that "plate modulation is the only way to go" has more to do with not coming to grips with the fact that it is about how much power we can put into the antenna and not how much plate input we run as in the past.

==========
Question : Do the new FCC rules, eg 1500 W PEP mean ,transmitter output power or power to the antenna , the latter meaning that any feeder losses may be compensated by a higher max. transmitter output ?

The latter is the case pertaining to the UK amateur radio licences. With a maximum output of 26dBW = 400 W PEP (on most bands) , in the case of 3dB feeder loss ,the permitted transmitter power is 800 W PEP.

Frank GM0CSZ / KN6WH (who has NOT read as yet the 'new' FCC max power rules)

Okay, thanks for that guys.
One clue that might assist in tracking down this problem is that the aforementioned arc that appears at about '37 minutes past the hour' on the outermost polar circle when the 50 ohm termination is fully screwed in first begins to appear at just before 12 o'clock and gradually circumambulates around this outer circle anticlockwise to its final position as it's fully screwed home. I'd have (intuitively) thought that once the centre pin makes proper contact with its counterpart, the trace would suddenly flick to close to the centre. But with no experience of VNAs, that's just a hunch. Any suggestions?

The FCC allows broadcast stations to compensate for losses before the antenna, but not amateur stations. You are legally limited to 1500 WPEP output at the transmitter.

Dave Platt wrote, among other things,
"In either case, if you screw an N male connector with a bad center pin into an N female, the male's pin can force the split segments of the center female pin outwards. Once this happens, a _good_ N male connector's pin may not make reliable contact with the female's damaged center pin. Intermittent nastiness can occur."

I've seen people suggest that you can mate an N plug with a BNC jack in a pinch, but what you describe is _exactly_ why you should never do that. The N plug center pin is a distinctly larger diameter than a BNC center pin.

Also note that there exist 75-ohm N connectors. Do not try to mate them with 50 ohm versions. A 75 ohm plug in a 50 ohm jack is likely to not make good contact, and a 50 ohm plug in a 75 ohm jack may cause damage to the jack.

Suggestions? You bet! Get out your RFSim99 and build a model of what you are putting on the RT test set test port, including any connecting cable. Play with the model to see what will get you the sort of performance you are seeing.

Note that you haven't really told us what you are plotting. I'm assuming it's a plot of the complex reflection coefficient on a display that's scaled to a unit circle. Are you using a standard Smith chart overlay?

The normal interpretation of the result you describe, however, doesn't make much sense, since the load seems to go from something like a nearly pure inductance with reactance equal to the reference resistance at the center of the plot (50 ohms?), and wanders around to become a very low impedance (at the left edge, -1+j0 reflection coefficient), and then around to become capacitive with moderate reactance (35 ohms?). Could you possibly be using some other scaling? What happens if you are trying to display a value beyond full scale on your display?

I suspect something is not what you think it is in the measuring instrument, and from past experience, I'd say it could be just about anything. Careful visual inspections often reveal problems.

Cheers,
Tom

Gary,

I think you are on to something. On another group I ran across something similar, and this guy rated his amp at 100 watts AM or 180 watts PEP. I never got through to the guy. In his defense, CB'ers rate amps on 'S' meter reading, not audio quality, bandwidth, or harmonic suppression. With that crowd, a keyed mic that pins the 'S' meter rules.

I am pasting one of my emails to the dude:

"andy" <pirateradiofm@xtra.co.nz> wrote in message

> amp.
>

Andy,

You are correct that I haven't seen it, or tested it. I don't have to. The specifications you supply are impossible to achieve. Your math is wrong. I'll go through this again:

>Power levels: 100Watts AM, 180Watts PEP

** If the power is really 180 watts PEP, then the AM carrier power maximum is 25% of that or 45 watts ---NOT 100 watts. In fact to be clean, and linear I wouldn't run more than 25 watts output on AM (100 watts PEP).

FACT: When you modulate AM with voice to 100% positive modulation, the peak power rises 4X from the carrier power, and the average power rises about 10-15% depending on the voice, and level.
FACT: When you modulate AM with a sine wave to 100% positive modulation, the peak power rises to 4X the carrier power, and the average power rises 50%

These 2 facts assume the amplifier has the upward headroom for 4X the power from the resting carrier level. Your amp cannot do this unless you de-rate the AM power to < 50 watts (more like 25), OR reduce the maximum modulation percentage to something much lower than 100%. . Here is a reference on this:

http://www.icycolors.com/nu9n/am.html#4:
If we produce a 100w carrier, and the modulation level is at 100%, the peak envelope power is 400 watts. But, the peak envelope voltage max is twice the peak envelope voltage of the carrier alone. So, for example; if the carrier alone produced 20v RF peak to peak, then 100% positive modulation will produce 2 x 20v which equals 40v peak to peak voltage.
Since power changes with the square of the voltage, then the power during 100% positive modulation will increase by the square, so the power increases 2 squared or 4 times! So, 100% positive modulation will produce 2 times the RF voltage and 4 times the RF power.

So Andy, do you want to stand by your specifications as is, or revise them? Do your specifications assume the amplifier is being overdriven, or are you asumming the amp is kept linear by reducing the modulation percentage? You cannot have 100 watts AM and 180 watts pep without either splattering like crazy, or reducing the modulation percentage considerably.

My earlier comments about splatter and distortion are important. To some in the CB crowd, they would rather emit a distorted S9+40 signal instead of a nice clean sounding S9+30 signal. To them bigger is better. I think we all know what crowd your trying to market this kit to, and as others have pointed out, this is the wrong place for that.

I recall a similar amp in Motorola application notes from the late 1980's, and it was marketed by Communication Concepts for many years. This was a well engineered amplifier, and the application notes had full specifications, and scope pictures. Even this amp had gain compression on AM, even though the AM power rating was much lower than yours, and the PEP rating was similar. I'll try to find that big fat blue Motorola RF power book tonight. I think I still got it.

Andy, since this forum is for posting schematics, and talking technical about them, please post your schematic. I look forward to seeing it.

Regards,
Jim

Sounds like someone has mixed 75 ohm N connectors with 50 ohm N
connectors.

50 ohm N males will damage a 75 ohm N female by spreading its contacts,
often to the point of damage.

75 ohm N males will fit loose in a 50 ohm N.

Many people obtain N connectors without actually knowing which one they
are getting.

Oh dear. It appears you may be right.
I've just checked with the suppliers and they tell me the plugs I bought are 75 ohm ones. This really stinks as in their catalogue, although they don't specifiy the impedance of these plugs, they do clearly state that they're suitable for RG214 coax. AFAIK, RG214 is only available in 50 ohm - if anyone knows otherwise please tell me. It took me a good deal of time and trouble to make up these patch leads so all in all, I ain't exactly pleased.
Here's the URL for the catalogue page so you guys can tell who's at fault here:

Hi All,

I acquired a Pitch-Prop motor a number of years ago, with the intention of building a antenna rotator.
I still have the intention of doing this, and have checked the motor for operation. This works out very nice, and was able to control it to different speeds with different voltage.
I have a construction design for the mounting of the motor and gearbox to the tower, and antenna.

The problem I have now, is I wish to construct a suitable control unit, with digital readout, and the possibility of controlling via a mini PIC control, or via PC.

I have searched the internet without much success, so my next course of action was to see if anyone on these groups might be of help.
So I put my hands up for HELP! :)

Any help would be gratefully received.

Thanks in Advance.

Kevin, ZL1KFM.

Replace the meter scale with a white card and calibrate it yourself
with pen and ink. You will also need a signal generator and an
attenuator.

Don't forget, an S-meter is a power or wattmeter. It indicates signal
STRENGTH. S9 = 50 pico-watts.

Since posting earlier I've been on to the actual manufacturers and they
reckon these plugs are actually 50 ohms. So the supplier's insist
they're 75 and the makers say they're 50! I need to know for sure, as
one or the other is in error. How can one tell, by visual inspection
and or physical measurement, which type is which? There must be
something that's visibly different about the two types.
THanks.

Yes, look at the thickness of the central pin. A 50 Ohm connector has
a central pin of some 1.6mm thick. The 75 Ohm version is a mere needle,
something like 0.8mm.

It's one of my long-time gripes about coaxial connectors that N and
BNC series of the two impedance levels are sufficiently compatible
to mate together, but not enough to do so without damage. In a lab
with someone ignorant of this fact, it's a source of endless trouble.

==========
Allison, I'm afraid you are not quite correct about coincidences.

The beauty of calibrating an S-meter in watts is that the result is independent of receiver impedance.

Of course, there must be a conjugate match between antenna and receiver. And there usually is. This is taken care of in the calibration process.

The received signal STRENGTH is indicated in watts, which is all one wants to know. When reading the meter, who cares about what impedance the measuring instrument happens to be?

To sum up : There is a transmitter of given power output. There is a radio path which is an attenuator, And there is a received signal signal strength meter which indicates watts.

The overall loss between transmitter and power meter may be deduced in terms of decibels. Professional radio engineers do it all the time.

It can be misleading to think in terms of S9 = 50 uV when one doesn't know what the receiver input impedance is.

If you derive the S-meter reading from the a.g.c. control voltage, be prepared to perform the calibration at various temperatures, since the gain of simple IF-strips vary with temperature (and thus need a different amount of a.g.c.), unless the gain is controlled by passive components only.

With various front end filter for various frequency bands and attenuation depending of the frequency, you would have to perform the calibration on several frequencies.

Instead of a pen and ink, it would be more practical to use a micro controller with sufficient non-volatile storage for the conversion tables and use analog inputs for a.g.c. voltage and temperature and some kind of input for the frequency being received. With these inputs and the conversion table, a voltage proportional of the log of the antenna terminal power could be generated.

Excepting the readout, this should be a fairly routine motor control problem. Depending on what you want to do your control box could be as simple as a current-limited power supply and a couple of switches or as complex as a fully fed-back motion control system.

How's your electronics skills, and how fancy do you want it to be?

Thanks, Jeroen.
Well on that basis, all the plugs I have here are indeed 50 ohms, then.
In fact I pulled a centre pin out of a new packet from the same batch
and it fits the sockets in the VNA perfectly. They all accept the pin
with a nice snug fit and what's more the sockets show no signs of ever
sustaining any damage/spreading/flairing/bending and that goes for
those on the T/R bridge, too. On reconnecting everything, however, the
problem still persists, although the 50 ohm load is now showing as very
close to a dead short; virtually the same spot on the Smith chart
overlay as when the socket is shorted, in fact. Once again, the other
loads do likewise and they all check out fine as 50 ohms with a DVM.
Very strange! I wonder if there's some setting I may have got wrong
somewhere. :-/

==========

The accuracy of S-meters varies from one band to another because the receiver input impedance varies from one band to another. Even from one end of a band to the other, especially if the input stage is tuned.

Also, the stage-gain of an RF stage can vary very much from one band to another.

To ensure a consistent gain it is necessary to convert to the intermediate frequency (IF) at the very first stage of a receiver. Preferably using a high-level, balanced diode-bridge, modulator.

The IF stages can be assumed to have a constant, wide-band gain, except, of course, for the automatic gain control (AGC) action.

Then ensure that the receiver input impedance is constant (usually 50 ohms) over the whole HF range of the receiver. Remember the S-meter is a power or watt-meter.

It so happens that with dual-gate FET's, and 3 or 4 IF amplifier stages, a meter which responds to AGC volts will fairly accurately indicate S-units and dB above S9 in a linear fashion.

However, below about S4 the linearity of S-meter readings begins to fail. And you will have to make and calibrate your own meter scale. There's no way of avoiding it! That is unless you can mentally visualise what the scale ought to look like as you use it.

Accurate commercial field strength meters use antennas dedicated to the job, conjugate-matched to the receiver, are insensitive to weak signals, are narrow band and are very expensive.

To obtain an S-meter scale to be proud of, you will have to use pen and ink with a signal generator and 100-dB stepped attenuator. Attempts to calibrate the scale with clever, highly complicated electronics will get you nowhere in a long time. And will cost you

more than the remainder of the receiver.

Sorry to be so despondent.

I don't doubt that the problem is capable of being solved.

Just throw enough electronic hardware and software at it.

The cost can be estimated at 100,000 Euros.

The size and weight of the receiver will be quadrupled.

No amateur would be able to afford buying one.

American tax-payers would prevent NASA from doing the research and
development work. Even Bush would object.

As for me and most other amateurs, I'm quite happy with an S-meter reading which puts signal strength reports in the right ball-park. Very strong, very weak, or indifferent.

I'm going to recommend against electronic feedback unless you are a control systems hobbyist... I did PID (proportional-integral-derivative) servo on a homebrew rotating mast so I didn't need a readout and eventually decided to go with a rotation sensing pot, a voltage-to-current converter, and a surplus meter.

This was after I tweaked the PID to get rid of the oscillations but still had some average position errors...

I guess with a digital system it would be easier to optimize. Mine was all analog... and only one op amp, so the settings interacted :-)

Making the motor go and watching the meter is a more sensitive and intelligent form of feedback, as long as you've got a system you can't break by turning too far.

A simple pulse-width-modulator for speed control might be in the cards though. That way you send a variable duty cycle full-on full-off pulse train to the motor. Good torque and you don't need a variable power supply just to run the rotor.

I'm going to add one to my rotator soon... I've got that on manual right now... pulsing the switch makes a nice slow smooth rotation!

If you do like electronics projects for the sake of electronics projects, feedback control is an interesting way to go, though.

Will take a look at URL:
http://www.ac6v.com/sunit.htm

Maybe the National Semiconductor NE604 IF amplifier IC would be worth looking into. Claims say it provides an accurate signal strength logarithmic output that closely tracks the input signal level over a wide dynamic range that could possibly be used for driving an S meter circuit.

Hi Dan,

If anything, going digital has all the prospects of thrashing the
antenna into shreds. The oscillations you speak of are eminently
suited for an analog solution - you simply have to understand the
nature of resonance, coupling (over, critical, and under), and attack.
If you don't, translating them into binary code will be impossible.

For instance, your average position errors were probably due to
under/overshoot and a too heavily dampened system with too much gain.
No computer program is going to improve that.

Paul-

What would be the result of calibrating the system with an inductive
"short"? If it can be done, results of testing with a good 50 Ohm load
might be skewed.

Richard,
Agreed on the suitability of an analog solution... I certainly made some steps toward critically damped operation. My circuit design was bad, though.

I didn't have a very analyzable problem; the rotator rotates one of those fiberglass surplus military masts with respect to another, so I get a lot of stick-slip, especially if there's a breeze (there are 12 feet of mast above this thing).

This is not to say a suitable set of P, I and D couldn't be found, and it would have been pretty slick if I'd set up right for empirical loop tuning, but I hadn't done that. I got pretty close by soldering components in and out.

I would have had a better time with a real multiple op amp circuit with a knob for each of P, I and D.

I think you hit the nail on the head regarding too heavily dampened with too much gain in the antenna rotator case. I just couldn't really tune the thing.

In my case, I just decided to throw up my hands and go to the simplest method so I could get on the air with a rotating antenna. I have a quite successful analog servo going every day with my remote antenna tuner (www.n3ox.net/projects/servo). That one is ever-so-slightly underdamped, proportional only, and works nicely. There's a little bit of hysteresis and it certainly could be improved, but I stopped at the good-enough-for-daily-operation level.

I guess what I meant by "going digital" was that depending on whether you're more comfortable with programming than a soldering iron (not me!) you might think about having a simple motor drive circuit and implement the admittedly complex PID loop in software/firmware.

You're absolutely right that you can't do this if you don't know how to do the analog...

Allison-

Such is life. However you can assume that both are 50 Ohms and use a resistive pad between the signal generator and the receiver when calibrating. When making a reading, use a pad between the unknown signal source and the receiver.

Without a sophisticated system capable of determining impedances while making measurements, this may be the best you can do.

Having had a look in my (junk)box with N-connectors I found that most
silver plated (professional) units have 50 Ohms stamped into the body
,whereas the nickel plated units either have no identification or a
specific manufacturer's code .
The Farnell catalogue you referred says these N-connectors are nickel
plated . Try to find any stamped code on your units . If any I'll be
happy to compare with those on my connectors.

That's why for the HF bands S9 is defined as a receiver input signal of
50 microvolts at 50 Ohms input impedance , translated as -73dBm
For frequencies higher than 30 MHz S9 is defined as 5 microvolts at 50
Ohms input impedance , translated as -93dBm.

The S9 signal strength was first set by Art Collins of Collins Radio
fame during the 1940s and was later accepted by IARU.
This organisation also adopted the 5 microvolt level for a S9 signal for
VHF and higher frequency bands.

Just an idea ; if one is really 'dead keen' to have an 'accurate ? '
S-meter readout, you could construct an indicator with individual
threshold opamp comparators (up to 4 in a DIL package) each driving a LED.
When calibrating with a signal gen as a 50 Ohms source ,starting with
S-9 being 50 microvolts being -73dBm (or 5 microvolts being -93dBm for
VHF and higher) the relevant LEDs can then be set separately below that
level with 6dB steps and above S-9 with 10 dB steps by accepting the
quasi-log voltage range generated by the AGC as fed to the traditional
analogue S-meter
A fancy feature would be different colour LEDs showing signal strength
above S-9. I feel that ,while accepting any 'professional'
comments,this would be a practical 'amateur ' (low cost) solution .

==========
Talking rotor position feedback ,instead of the traditional potmeter in bridge circuit with analogue meter readout ,you could try a low cost synchro system utilising 2 stepper motors from discarded hard drives , dot-matrix printers or flat bed scanners ,with 1 stepper motor mechanically coupled (either directly or via a reversed rotational reducer) to the rotor ,the other in the shack as a readout device. The circuit I found on the web (via Google)needs 5 wires between the stepper motor coupled to the rotor and the control unit ,located with the other stepper motor in the shack.
The circuit includes 4 TIP120 NPN transistors 2 LM324 dual Opamps and a few diodes and resistors. The stepper motor in the shack could either be provided with a rotating or sliding pointer (the latter from an old 1950-60s radio) , or be mechanically linked to a counter (for example from a discarded tape recorder)

A potential 'recycled components' project.

Good thinking, Fred. That's theoretically possible, I guess. But I'm carrying out these checks purposely at only around 5Mhz to minimise such high frequency effects. You may well be on the right lines, though!

This is ok, but the one thing is that any Signal strength IC like the 604 has a constant slope and the S-Meter will be rather compressed in the 0-9 s-units range compared to the over S9 range (obviously fixable with meter scale). I don't recall the 604's dynamic range. You could make a two slope correction above S9, but I'd have to do some scratch paper work to figure out the circuit [probably as simple as a resister and diode in the right place]. Or use two of them and change the gain into one to get the different slope. I don't recall the 604's dynamic range. I have some SLx16...oops can't remember the numbers (? 1316?... 1613?) , that are cascaded for large dynamic range log amps.

Just some ideas.

Mike,
I'm confused. The "crowbar" I am familiar with is an over voltage protection device. If the supply output voltage goes up too high, it triggers, turns on providing a very lo resistance load and effectively shorting the output. Thus it initiates the over current protection device, whatever that is.

If I read this correctly, it appears you are PLACING a short on the supply and testing the over current protector...

It sounds like "Crowbar" is also used for an over- current protector...

I always thought the term came from using a real 1 inch diameter steel crowbar (the tipe used in Christmas Story to open the crate containing the leg lamp) to short the output of a power supply as a really good way to get to zero volts in a hurry - but only in principle, of course.

You're on the money as to what gets done to save the IOT. It's a lot
more expensive than the entire power supply, and so the PS gets to
suck it up between the time the hydrogen thyratron (or ignitron or
whatever) turns on and the time the overcurrent limiter or magnetic-
controlled breaker on the PS input decides to Turn Things Off Right
Damnit _Now_.

You're also on the money about crowbars being used as overcurrent
protection as well as overvoltage protection.

My experience with crowbars involves both the voltage-foldback flavor
and the current-foldback flavor. Sometimes you'll be running something
at constant current and want to limit the voltage across it; for that,
you fold the curent back to keep from exceeding the max voltage.
Sometimes you'll be running something at constant voltage and want
to limit the current through it; for that, you fold the voltage back
to keep from exceeding the max current. In the extreme case, you cut
the voltage across, or current through, a device off by putting a
short across the PS output. We had some lab PSes at the NASA Manned
Spacecraft Center with adjustable voltage _and_ current limits,
though none with high-capacity crowbars involving ignitrons, hydrogen
thyratrons, and such (to me) exotic devices. But both voltage and
current limits came in very handy.

Hi Tim,

My electronics skills are fairly good, I have built many projects over the time.
What I was wanting to do, is have a control box in the shack with a readout and left/right controls. And have the provision to also be able to have a PC control it.
I like the Pitch-prop motor, as it is strong, and can be controlled easy.

The way I control it at the moment, is via a 2 voltage system.
The pitch-prop runs at 36volts for full speed, and when I wish to slow it down for small movements, I use a second set of controls at 15volts. Not the best way of doing it, but it works.
I then look out the window and see where it is pointing. I know where N, E, S, W are on my section.

As to price on the parts, I would like to keep it down to around a couple of hundred dollars. :)

Regards and thanks for your input.

Source record: 12038

The way that spectrum analyzers are built is typically to use calibrated attenuators and linear gain stages that have very low distortion (and similarly low "compression"). Then it becomes a matter of determining the voltage after amplification. They do NOT use AGC voltage, or at least not anything like the AGC used in a typical ham receiver. The way we do it here is to digitize the RF signal and do some appropriate digital signal processing on it (e.g., FFT) to display the spectrum and to calculate amplitudes and band powers and the like. Modern digitizers are very linear indeed and can be used to measure signal amplitudes over a range in excess of 120dB with relative accuracy far better than an S meter over most of that range, and still considerably better even at the bottom end of the range. It doesn't even take a huge number of bits in the digitization to do it; consider that a typical delta-sigma ADC is a one-bit converter followed by lots of processing gain.

The way it can be done "on the cheap" is to use a calibrated attenuator and a single known signal level. Then you compare your known signal level with the unknown, adjusting the attenuator to bring your (typically large) signal down to the same amplitude as the unknown.

For S-meter levels of accuracy, linear non-AGC'd stages feeding one of the RF power detectors from Analog Devices, Linear Technology or others will work fine. Most of them have an output voltage proportional to the log of the input voltage, and so can be calibrated to read dB linearly on a linear meter scale. If your receiver has a good front end, it shouldn't need AGC up through the filter following the mixer, and you could pick off there after the filter to drive the meter circuit. That seems overkill, but it would get you a _good_ S-meter. Then you'd have to calibrate out the front-end gain at least per band, assuming you have at least some front end filtering that doesn't have the same gain (loss) on each band.

Field strength meters that accurately measure an RF electromagnetic field are basically spectrum analyzers fed by calibrated antennas.

That may be beyond what you wanted to know or do, but it should give you a pretty accurate picture of how modern commercial gear actually does make RF voltage measurements. You could add calibration (for absolute amplitude accuracy as well as spectral flatness) to all that as a whole 'nuther topic, though. For example, the amplitude characteristics of any filters the signal passes through in the spectrum analyzer must be properly accounted for, as must temperature drifts in instruments with high accuracy.

Cheers,
Tom

Hey Kevin:

http://www.wescottdesign.com/articles/pidwophd.html
http://www.wescottdesign.com/articles/Friction/friction.html

If you want to control it from a PC I'd suggest that you drive an H bridge from a microprocessor, with a PID controller in there to make it go. The biggest key to making a PID loop without doing a bunch of math is to keep your ambition under control -- if you have to go fast, then you need to delve into theory.

As pointed out, PID control can be tricky -- even though I'm a control systems professional there's a good chance that if I did it rev 1.0 would just use the micro to implement virtual buttons, with feedback control for rev 1.1. You definitely want to make sure all the pieces are working before you close the loop.

Source record: 12042

I think I'd follow K7ITM's advice.

I'd split the signal right after the IF filters. Feed one of them into the rest of the Rx chain, and the other one into one of the Analog devices logarithmic detector chips.

This is assuming there is no AGC prior to the IF filters.

There are two major choices for the detector chip, AD8307, which is a power detector, or a true RMS detector (AD8326??)

Feed the output into a A/D coinverter, and then digitally add correction factors for the front end gain and possible different sensitivity on different bands.

So, once you have the calibration factors, this wouls be a fairly accurate iindicator of the input signal. Granted, it is assuming a matched 50 ohm antenna, and you will get an error due to antenna reactances and so on. However, it is as precise as an amateur radio system is likely to be able to get and a heck of a lot more meaningful than most 'S' meters I've seen.

Have you tried buzzing your home-made leads through with a DVM to
confirm that they're ok (at dc) - both centre and shield of the coaxial
connectors?

Try discarding the test-set for a moment and just connecting Ref to the
A and B inputs on the VNA (configured to measure loss/gain). If you know
that your coaxial leads are ok, then you'll be checking that all the
I/O ports on the VNA are working correctly.

Have you confirmed that the test-set is correctly connected to the VNA?

Try terminating unused I/O ports with a 50 Ohm load or with a pad (a
10dB pad makes a reasonable 50 Ohm load) and then repeating the cal
and measurement.

Try calibrating the VNA/test-set without the leads, just using a
Male-Male adaptor instead. Then see what happens when you measure gamma
with 50 Ohms dangling off the adaptor.

Cheers,
Rick

All the 75 ohm BNC connectors I have, have the same diameter center pin in the connection region as 50 ohm connectors. The difference is in the thickness of the dielectric around the pin in the connection region, being much thinner in the 75 ohm connectors. The pin of the 75 ohm connector is smaller only where it's in solid dielectric at the bottom of the connector.

I don't know the underlying cause, but I do see the same outage here.
The server for "eham.net" doesn't respond to pings, although the two
machines with immediately-adjacent IP addresses do.

Looks as if the server's off the air.

Hi Roy,

There's lots of room for confusion. The Kings tool FAQ implies the
center contact diameter got smaller when the pin was redesigned and
the old crimp die set would not work:

~~~~~~
Why won't my Kings 2025-X-9 die set work with the 2065-X-9
connectors?

With the redesign of the True 75 Ohm BNC connectors, the center
contact diameter got smaller to maintain a constant 75 Ohm
impedance through the connector. Consequently, the center contact
crimp dimension got smaller also.

The problem with the inability of the die set to crimp this new
connector is probably because it is the older, larger die
dimension. The Kings website has a Cross-Reference Search that
lists the applicable die set for most Kings connector part
numbers.

http://www.kingselectronics.com/ResourceGuide/FAQs/tabid/74/Default.aspx

~~~~~~
However, another manufacturer claims their new 75 ohm hardware is
interchangeable with 50 ohm connectors:

~~~~~~

TRUE 75 Ohm BNC & Connectors

Where Controlled Impedance is a Necessity

Emerson Network Power Connectivity Solutions is introducing its premium line of TRUE 75 Ohm BNC connectors and adapters. These flexible cable 3 Piece BNC Connectors are essential for analog and digital high frequency signals.

They have been designed around MIL-STD-202 for up to a 3GHz frequency range, and are constructed of high performance materials including a machined nickel plated over brass housing, a teflon dielectric and gold plated brass contacts. These connectors are designed to eliminate distortion and impedance mismatching caused by using 50 ohm connectors on 75 ohm cables, and they safely inter-mate with standard 50 Ohm BNC connectors.

http://emersonnetworkpower.com/webapp/wcs/stores/servlet/ESC/pdfs/True-75-Ohm.pdf

~~~~~~

If your junkbox is anything like mine, it may have stuff purchased 20 years ago mixed with more recent purchases. So it might be worthwhile to check carefully before mating different hardware.

So the thought finally strikes me. How do you check the female socket dimension? Do you stick a male pin in and see how much friction there is? That could bend the contacts and damage the pin.

How about checking the male pin diameter when it is already installed on a connector? There's not enough room for calipers to reach the pin.

I often find the BNC connectors on my scope go intermittent due to a loose center pin. Often the only choice is to use a pair of pliers to squeeze the contacts together again. The damage appears to have been caused by some off-brand 50 ohm terminators that require an unusual mount of force to seat on the connector. But the repair doesn't last. Once the female pin has been forced open, it quickly goes intermittent again. This is a big problem since the scope connector is usually a special item that is difficult to get.

While NASA might have needed such sums in the 1960's, the
functionality suggested above should be doable these days with any
micro controller with a few kilobytes of non-volatile storage.

While the frequency, power level and temperature calibration points might require a three dimensional array, in practice, it should be acceptable to get a few single dimensional vectors for each amateur band. One vector for a specific band might contain the front end frequency response for 5-10 frequencies within and around a band.

Getting the a.g.c. setting for different power levels for a fixed station at three different temperatures (say +10, +20 and +30 C) or five for a mobile station (with additional values for, say -50 and +70 C) should be enough. A few kilobytes should be more than enough to get the sample points for interpolation.

>As for me and most other amateurs, I'm quite happy with an S-meter
>reading which puts signal strength reports in the right ball-park.
>Very strong, very weak, or indifferent.

Exchanging RS(T) reports is so stupid, so I try to avoid it.

The only meaningful exchange would be to exchange the field strength (V/m) or the power density (W/mï¿½) in order to study the propagation conditions. Even if we could reliably measure the antenna terminal voltage (e.g. in dBuV) or power (dBm), we still would have to measure the antenna efficiency and capture area to get any meaningful readings.

For sure. It looks like it's not safe to mate a 75 ohm connector with anything, even another 75 ohm connector, without checking pin diameter.

Maybe your "N" female connector has "splayed" leaves on the center
contact. This sometimes happens when someone tries to screw a PL-259 UHF
connector in place by accident.

2956. Suggestions how to fix a 2-m xcvr problem?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-24 23:07:48 UTC
From: mcalhoun@ksu.edu
Message-ID: <e52p04$6m0@unix1.cc.ksu.edu>
Source record: 11958
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

NOTE: Crossposted to rec.radio.amateur.equipment and rec...homebrew.

For some years, I've had a Kenwood TM-251A 2-meter xcvr (with 440 rcv) hanging from the ceiling of my pickup truck, and recently the TouchTone pad (in the microphone) quit working and, while PTT causes plenty of RF output, there's no AUDIO output.

I'm pretty sure the problem is in the microphone electronics OR its 8-wire cord. I've "beeped" the cord from the telephone/data-like (RJ-45?) connector to solder joints on the mike PC board (it's quite a full little board!) and don't find anything wrong (but it's hard to hold a probe on each end and wiggle everything in the middle!). I'd replace the cord in a flash except I can't handle that %$#@! RJ connector.

The only microphone detail in the xcvr Service Manual other than the connector pinout:
UP
+8 volts (I measued +7.25)
GROUND
PTT
ME (Mike Earth?)
MIKE
RD (Read Detect? An output, perhaps for use with a TNC?)
DOWN
is the fact that PTT, UP, DOWN, CALL, VFO, MR, and PF are connected to three analog-inputs (and ground), thus "using up" four of the seven input wires and leaving just two wires (MIKE and ME) to handle the remaining 16 TouchTone keys AND audio!

PTT, UP, DOWN, CALL, VFO, MR, and PF do work as they are supposed to.

With "Remote Control Mode" ON, letter "A" on the TT pad is supposed to start frequency input from the keypad, but it does NOT. With an oscilloscope probe on the MIKE and ME wires, pushing "A" gives no visible change in the trace, but my jury-rig setup would probably miss a single tone-burst, so that is probably an inconclusive test other than the xcvr CPU didn't respond, either.

Any suggestions?

Or even 50 ohms, for that matter. But how do you check the pin diameter on an existing connector? A caliper won't go in there. Also, the diameter could be correct but the pin could be assembled incorrectly and stick out too far. This will damage the female pin.

Or maybe you know of some other non-destructive method to tell if you can mate an existing male and female coax connector without damage?

The vulnerable part is the female pin. Once those legs get splayed there's no way to put them back. All it takes is one event to effectively ruin a brand-new scope.

Well, a scope will have a 50 ohm female connector, which should tolerate
any kind of male without damage. The only vulnerable connector should be
a 75 ohm female connector of the sort which has a smaller pin diameter.
I don't believe I've ever seen one of those, and you'll certainly never
see one on any commercial equipment except only possibly some
video-related units.

> tolerate any kind of male without damage.

That's what I was talking about earlier. I ruined the BNC inputs on some of my older TEK scopes by using off-brand 50 ohm terminators that were difficult to install. Apparently the male pin extended too far into the female and spread the pins. Some cheap commercial coax cable had the same problem. The scope bnc connectors are special and had the multiplier contact for 10X probes, and were too difficult and expensive to get and install.

I would often waste time debugging strange waveforms when it turned out the problem was in the scope connector. Squeezing the pins gently would make it work for a while, then it would come right back.

You often see the problem on used equipment like spectrum analyzers, sig generators and counters. Evidently someone went in with needlenose pliers to try to tighten the legs, but instead squashed them into a square instead of a circle. They don't make reliable connections after that.

After discussing this, I'm inclined to get a handful of female connectors to test the male coax hardware. If it ruins the connector and cannot be fixed, toss it in the garbage where it belongs.

That's good - I don't think I've ever used or seen any 75 ohm hardware, but maybe someone working on TV might run into the problem.

I did get through yesterday morning, but incredibly slow. Now (Wed
night), I'm getting "The connection was refused when attempting to
contact www.eham.net", despite successful pings to server. This
sometimes due to max number of connections has been reached.

More info:

Have you checked at the rig end? I've had broken or intermittent
connections to the mic socket - the socket pins have poor soldered joints.

Bob

Saturday May 27th, 2006

Annual Spring Hamfest Located at:
Westwood Regional High School
701 Ridgewood Road
The Township of Washington, New Jersey 07676

8:00 AM till 2:00 PM
Rain or Shine- the Hamfest will have Indoor spaces and Outdoor Tailgating spaces.
Amateur Testing: Novice thru Extra 8:00 AM to 10:00 AM ONLY,
Please bring original FCC license, a photo-copy and photo ID.
The fee for Amateur testing is $14.00
DXCC Card Checking courtesy of NJDXA
Admission is $5.00 per person (wives and children free).
Vendors $15.00 (per space- includes one free admission).
No reservations are required for these spaces.
A limited number of Indoor spaces are available with electrical power.
You must reserve these spaces in advance.
Lots of Parking
Lots of great Bargains and Goodies.
The Hamfest is open for vendors at 6AM, and at 8AM for buyers.
Rest Room Facilities
Refreshments
Talk-in on 146.19/79 Repeater PL 141.3 & 146.52 Simplex

It uses the LMX2306 PLL chip with a VCO, presumably. As the tuning
range is limited to 10%-20% of the centre frequency the phase noise is
probably quite low.

The website owner doesn't choose the ads to appear, Google does that
automatically, based on keywords.
But Google adSense has a filter option to trash any undesired ad. A simple
matter to put the "offending" ad in the filter list.

Eham has been a valuable resource for hams. With the high cost of running a
Mega Site such as eham, I suggest we support the site, otherwise it may go
away.

You will notice a lot of the Ham Megasites are using Google AdSense. Why?
It is bloody expensive to run a megasite. When the site gets popular, a
"Normal" provider will add outrageous costs for excess bandwidth, forcing a
web master to get a server. Servers ain't cheap. There are other costs as
well, main provider, link checkers, domain name costs, computer maintenance,
anti-virus checkers, software, etc.This says nothing about the Web Master's
labor to keep the site running. Many of the mega sites are free - such a

deal.

AND - you buy a magazine -- full of ads, Movie rental - full of ads, cable TV - full of ads, etc.
I suspect the ads income on Mega Sites don't come near the covering the cost of running a Mega Site. Even if it did, so what - you don't have to click on the ads or read them. Can't do that with magazines (;-)

You miss the point.

ALL Google ads are BPL adds. Google uses the money they get from Adsense to finance BPL networks. That's right, Google invested a lot of money in BPL. Using Adsense supports BPL, using Google supports BPL, buying Google stock supports BPL.

Got it? Google and BPL are connected.

As for supporting those sites, "you pays your money and you makes your choice". A click on a Google Adsense ad helps pay for BPL. There are other online "click here" advertising companies. He chose Google. I chose not to support him.

IMHO it's like running a pro-enviornmentweb site and using the proceeds from advertising to fund toxic waste dumping.

Geoff.

Well if I boycotted every biz that had policies I disagree with, wouldn't be
alot left.

So your quarrel is with Goggle not e-ham.

Strange but just about every major Ham web site is now using Google AdSense.

Guess you will have to start up your own Ham website

We've built some equipment with 75 ohm connectors. In those network analyzers that use a separate S-parameter test set, you can often get the test set in a 75 ohm version as well as the more common 50 ohm. But the 75 ohm units are (as far as I know, _always_) labeled with a caution about using the right impedance connectors.

Cheers,
Tom

==========
I am not a supporter of BPL .....full stop.
Apart from that , in the UK (A)DSL is widely available ,so BPL (or PLC)
is not an issue eg a threat to Amateur Radio in this part of the world.
However there is BPL and BPL.
Most of us on this NG know that ARRL is fighting against the
introduction of 'certain BPL systems' which pollute the HF and up
spectrum ,but NOT BPL in principle.
On the ARRL premises Motorola have installed a BPL system that according
to ARRL does not pollute the spectrum .

So when addressing Google's support for BPL , it seems only sensible to
adopt a more balanced opinion .
Google is an effective search engine ,that's why I use it. There is no
other reason.

You've built a hell of a lot of it. All the stuff for the Telco's. like my
backup HP-313 that I mod'd back to 50 Ohms.

Tradionally S-9 has been defined as 50uV, but there
really is not a standard. The S numbers are taken from the
old R-S-T system of reporting signals (Readability,
Strength, Tone). While the meter can be calibrated using a
calibrated signal generator the reading for 50uV will vary
with the gain of the receiver so it will not be the same on
all bands or even from one end of a band to the other.
Some receivers have meters calibrated in something other
than S units. For instance, the old Hammarlund SP-600. The
meters on these are usually calibrated for RF in db above 1
uv. But, the same thing applies, the receiver gain varies
with band and frequency, the AGC is not linear, and the
reading only an indication of relative strength rather than
any actual value.

Well, yeah, I guess we have. In fact, not long ago I was cleaning up a lab bench and found some of the old Telco style connectors, all gold plated and pretty. I couldn't bear to toss them, even though the chances of us ever using them again are somewhere between slim and none, toward the none end of that scale. I suppose that any special-impedance market that was large enough, we built for. Of course the older audio generators (200CD et al) were 600 ohm.

Cheers,
Tom

The same in the United States. Due to the overspending on infrastructure without demand in late 1990's there is plenty of "dark" (unused) fibre.

> However there is BPL and BPL.
> Most of us on this NG know that ARRL is fighting against the
> introduction of 'certain BPL systems' which pollute the HF and up
> spectrum ,but NOT BPL in principle.

The problem with the system Google funded is that they do polute spectrum, just not ham radio spectrum (for now). Therefore the studies the ARRL has done which inlcudes going there and driving around show there is no problem.

If you think of Google's BPL as the electromagnetic equivalent of toxic waste dumping, the ARRL is more like the AAA (or AA in the U.K.) than Greenpeace. As long as they dump "off road", there is little they can do.

It is interesting that in this case, Ed Hare, W1RFI, the ARRL's BPL expert has tried to interest U.S. radio user's groups besides the ARRL and no one was interested in his data. AFIK the only country where anyone has complained about the effect of BPL on commercial traffic was Austrailia.

The problem is that the notching out of ham bands is something that can easily be undone. It may even be as simple as the operator of a system entering filter parameters into a control computer. In fact it would have to be, or they could not react to complaints.

That means there is nothing to stop a system operator, once they are established from using the ham bands.

> On the ARRL premises Motorola have installed a BPL system that according
> to ARRL does not pollute the spectrum .

I don't know much about it. I've read claims as such, that there is NO RF polution by the Motorola system, but have seen no hard data. If it does or not, the Google supported system does pollute, they just make sure that no one with an organized voice are the targets of their polution.

> So when addressing Google's support for BPL , it seems only sensible to

> other reason.

There are lots of effective search engines. Google has been terrible for a long time. When Google first started, you could put in a subject and get a hit on the first page for THE web site as opposed to it now being on the fourth or fifth page.

Geoff.

2981. Repairing moving coil meters.

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-26 15:01:20 UTC
From: dick on the langwang <dick@ravelrig01.demon.co.uk>
Message-ID: <1148655680.773573.261290@j33g2000cwa.googlegroups.com>
Source record: 11982

Has anyone experience of repairing moving coil meters and/or able give me to any useful pointers. One of my (many !!) restoration projects is being held up by an u/s meter & from inspection I suspect although the coil/pointer move freely one of the fine wire connections to the coil has gone open circuit, due to corrosion. I'm happy stripping down & repairing clocks but have no experience of doing the same to meters. In the end I'll probably have to find a replacement but it would be nice to try & get the original meter working again.

Caveat Lector wrote:

Eham has been a valuable resource for hams. With the high cost of running a Mega Site such as eham, I suggest we support the site, otherwise it may go away.

Good Riddance to eHam.
An unsuspecting ham posted the following on an email reflector.

Folks,

I wrote a short piece about the 'K2 versus all them big new rigs'

several weeks ago, but I guess it isn't going to make it where anyone

can read it on the front page or subsequent pages on eHam.

Perhaps sites that depend on advertising revenue don't like ruffled

vendor feathers? :-)

In any event, you can view and comment on it here:

http://www.eham.net/articles/8800

AB7RG of Eham took affront, and posted the following:

Actually, it was this comment, "Perhaps sites that

depend on advertising revenue don't like ruffled

vendor feathers?" -- that is what really did it.

Especially when:

http://www.eham.net/about/showadvertisers

Look seven down, that says it all...

Next time get your facts straight first, Jeff. Then

if you have a question or concern e-mail me privately

and I will be more than happy to let you know

approximately if/when your article will be posted on

eHam's homepage. Like I said, I can only run so many

at a time, and we receive TONS of submissions. And I

would have glady ran yours in just a few more days if

you had just been patient.

Bottom line: You show me some common courtesy and a

little respect and I will happily return it.

Now that would not be so bad, although he also removed the mentioned article from eHam in a fit of pique, and engaged in a bit of email harassment.

Folks,

There is nothing spooky or scary going on here.

I submitted an article on July 12 for publication on eHam. If you know

anything about that process it takes time and you also get an

auto-generated response telling you that your article "may" or "may not"

be selected for front page publication.

Given that it has been three weeks, and that other, more recent articles

have been published I just *assumed* that mine was not selected for

publication. They receive a lot of submissions and that wouldn't have

been unusual. So this morning, I sent the link to this list so that even

though the story didn't make the front page, other Elecrafter's could

read it. In my posting, I included the URL and this one comment:

"Perhaps sites that depend on advertising revenue don't like ruffled

vendor feathers? :-)"

I thought that the little smiley guy :-) conveyed that I was joking and

I wasn't actually implying that eHam was doing anything devious in

choosing not to publish the article.

However, the Articles Manager had a much different take on the matter

and proceeded to send me several emails that asked for my "respect" and

my "courtesy" or that article would be pulled. I told him deleting the

article would be fine with me and he has done that. There were several

other messages between us where he sent me the dictionary definition of

the word "libel" and such, and ended it all by saying that I was banned

from posting articles on eHam until I learn to be more courteous, and

that he was deleting any follow-up messages from me, etc.

Obviously I'm not thrilled by all this, and his public posting to this

list was an obvious attempt to "set me straight" in front of a public

audience. I wouldn't have replied at all but I started receiving emails

from this list asking why the link on eHam couldn't be reached and what

all this was about.

I would REALLY appreciate if this could end now. I have always hated OT

posts and long, meandering threads that have no value, and this one

certainly has none at this point.

I apologize to the list for the messages it has already spawned, and

hope that you will take my plea to heart and NOT FOLLOW THIS UP.

Thanks and see you all on the bands!

I also emailed AB7RG, and received a nasty email telling me I 'was not very smart' and reminding me of how he had to ï¿½throw me offï¿½ the Argonaut V reflector. He certainly did. I DARED to suggest that the ArgoV was not up to the performance of the Elecraft K2.

Then, he ï¿½modifiedï¿½ my profile on Eham.net, adding ï¿½and making trouble on eham.netï¿½ to my hobbies. When I saw this, I added under ï¿½Things I want to doï¿½ that one would NOT be contributing to eHam, when they dared to modify my profile. Now I see my profile has been totally deleted, and my email address changed to ï¿½JoeBlow@anywhere.com,ï¿½ to insure I can not re-enter it.

UPDATE

Now the arrogant, childish a**hole has fixed it so I can't edit my ï¿½Profileï¿½ nor can I post on any of the Forums. It is really sad that he has to do this to feel like a ï¿½big shot.ï¿½ I guess his ï¿½significant otherï¿½ must have laughed at the size of his......antenna.

Dick-

As I recall, current is conducted via upper and lower springs, to the moving coil. If you can determine that the coil itself is still conducting, you may be able to repair connections to the other components.

If the needle cannot be zeroed with the mechanical adjustment, it is possible one of the springs has broken or come loose at one end.

It would be handy if you have an Ohmmeter with a beeper, that sounds with very low current conduction.

(I've had very few movements with open coils, but have obversed several cases where plating of the pole pieces peeled and jammed the movement.)

As far as replacement, look near the bottom of the meter scale. You may find the meter sensitivity listed. It might be something like "FS=1mA" or "FS=50uA". If you determine the sensitivity, any meter with the same size and sensitivity may be useable by swapping meter scales.

Okay, I tried Dead Bug construtcion, and it seems it is absolutly
wortheless for complicated circuits. Most the hams I see pushing this
method are only using a couple components, try it with about 50, and
see how well it works---NOT. I made two of my systems with it, and an
amp, all are crappy!!

Good enough to get you in my killfile. Ah, the sigmonster has a truly
uncanny ability to choose an appropriate sigfile. This one must have
been chosen with you in mind.

Our local university club had one of these that was flakey as well, it had
been hit by lightning and both receivers worked, but from the testing I did

on it, the ptt no longer worked as ptt, one of the freq change buttons now worked as ptt, but locked on when pressed once, then turned off when pressed again. The other buttons on the mic were similarly mangled up. No one wanted to spend money to actually fix the piece of junk, so it just got shoved in a box and stored away. Good luck on getting yours running, I was not impressed by the recieve audio, and with the transmit problems with the one we had I never did listen to its transmit audio.
thanks, John.

Already know the sensitivity (250 microamps) but thanks for the tip about peeling pole piece plating, don't think it's that though because the coil/needle rotate freely. Reason I suspect the o/c is because there's a 'green, furry blob' (due damp storage sometime in the past ?) halfway along the fine coil connection wire, possibly surrounding a joint. Job for a fine brush & steady hand I think !!

I wouldn't even consider it for anything at all complex, although it
might not be too bad if you split the circuit into smaller modules
rather than trying to get everything on one board. I prefer what could
be called 'live bug' construction, with the chips the right way up. I
have a good home PCB process, so I tend to use that these days.

Perhaps the ghosts from your dead bugs are causing interference. 8-)

Listen at: http://www.ourmedia.org/node/229696

Background:
Tired of listening to Led Zepplin or NPR on your I-Pod? Wouldn't you like to be able to carry with you the kinds of ham radio conversations that you listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in London, England meet regularly on the ECHOLINK system to discuss their homebrew radio projects. We are making them available as PODCASTS.

NEW RSS FEED: You can subscribe to the program, have them downloaded to your MP-3 player, and listen to them at your convenience. To subscribe, just cut and paste this URL into your I-poder (or similar) software. We've been having trouble with our Ourmedia RSS feed, so Mike (software wizard that he is) has homebrewed his own RSS feed. In order to subscribe to SolderSmoke, point your podcast software to:

http://kl7r.ham-radio.ch/soldersmoke.rss

If you don't have an MP3 player you can just go to the site below and listen to the latest program (and earlier editions) using the audio software on your computer.

http://www.ourmedia.org/node/229696

Here's the homepage for our show. All our programs are available here. There is also a blog and links to some of the sites and documents we've been discussing: http://www.ourmedia.org/user/36170

We hope you enjoy the program. Please send us feedback.

73 from London

I just got a very good "homebrew" PCB process set up using gloss photo paper printed in a laser printer ironed onto the board for the resist and muriatic acid / hydrogen peroxide for the etchant. Is this the way you are making boards?

I have not worked on a meter movement in many years due to lower costs
replacements and better personal finances. When I did work on them I
recall being pretty successful.
If you spend enough time preparing, it almost always works out. The
safest way to verify an open movement is to take it in your hand and
see how much you can shake it around. If the needle shows a difference
in damping with and without the terminals shorted it is not open.

Bearing problems due to mechanical shock are common.

Broken pointers can be repaired with a tiny droplet of black paint.
Use a single hair from a paint brush to apply.

Be innovative, if you are motivated, it will work!

No, I use conventional UV exposure and FeCl3. With artwork printed on
an inkjet printer I can reliably do 8 mil tracks.

Thanks, Rene and nice to hear you're still posting here, despite all
the political BS that's sadly still thrown around by some of our
regulars.
I'm afraid this unit doesn't have any software as such; it's circa 1980
vintage (which is why it appealed to me as it's truly servicable with
no custom chips etc.). As for the spectrum analyser, I sold my last one
about 4 years ago and regretted it within 2 weeks. I've never replaced
it. :-(However, I still have some pretty mean scopes, so all is not
quite lost! What do you suspect the problem is: signal level or
spectral purity?
Paul.

I just flush it down the toilet. I think that ferric chloride is used for water treatment and I can't see the small amount of copper doing any harm by the time it has been diluted millions of times. It's only a litre ot so every six months - it's negligible.

Do you use the inkjet to print directly on transparent film? Is the
contrast/opacity good enough or do you need to stack two or more sheets?

I use a laser printer and OHP film. Even with the toner density set to
maximum, I find I need to use two sheets of film for best results.

I print directly on special JetStar film, from Mega Electronics in the
UK. Opacity is fine.

>
> I use a laser printer and OHP film. Even with the toner density set to

I never found OHP film much good when I used a laser printer, I used to
use LaserStar film or tracing paper. The latter is fine for most boards
and very cheap.

Yes, I know this is homebrew and not equipment - my theory is people who build also reapir/modify. (Thankfully, not all radios are menu driven YET.....)

Fixing a TS520 Kenwood for a friend - the 160m coil wont tune on receive alignment - how the hell do you get the RF board out to service the rotten thing? - its a mechanical nightmare!

>From what I can see, (to get it out topwise) its remove front panel, unbolt enought of the switches to enable you to swing it clear of the bandswitch. Then remove the 2 nuts from the fron of the bandswitch, remove the wafer, and then - nah, that wont work - still not enough clearance to get to the boards - if you could somehow manouvre the support shafts of the bandswitch assembly out of the way....(and I am not even mentioning the inevitable washers/spacers/nuts/small children that are going to fall into another time/space dimension...)

This is after dismantling all the preselector tuning chain drives etc, and the PA tuneing and loading controls.......woooo......

Otherwise, un wirewrap every one of the coil PCB's and lift it out that way .- from the bottom.

Anyone done it? - one of the previous owners hasnt, looks like much stuffing around with a big soldring iron and a small crowbar in there - not pretty....

There MUST be an easier way, or is this just a real pig of a radio....

Andrew VK3BFA.

Do you have the Kenwood Service Manual for this radio? If not, GET ONE.

Almost all of them show with pictorials and descriptions how to take apart
radio.
Some use exploding parts diagrams.

By the time you dump it in this way, you aren't dumping pure ferric chloride by any means! You're dumping a residual amount of ferric chloride, plus a bunch of copper chloride.

The waste-treatment authorities in this area are very much against having soluble copper dumped into the sewage system. The copper eventually ends up in San Francisco Bay (after having caused some amount of interference to the biological sewage-digestion/treatment system). Multiplied by a large number of potential sources, the copper load can have an injurious effect on the Bay ecosystem... it's toxic to algae and to many other natural microorganisms.

This problem can be prevented, quite easily, by simply titrating some sodium hydroxide (lye) or sodium carbonate (washing soda, soda ash) into the exhausted etchant. It may bubble a bit, with the bubbling ceasing as the pH rises to the point of being mildly alkaline (pH of 7 to 8... use pH paper to monitor). The copper remaining in the solution will precipitate out as an insoluble solid. Allow it to settle and pour off the remaining liquid... MG says that the liquid can now be poured down the toilet safely. The solid (copper hydroxide or copper carbonate, I believe) should be disposed of according to local requirements.

I've used the same precipitate-with-soda-ash trick when using sodium monopersulphate as an etchant (it's surely work with the somewhat faster-acting ammonium persulphate). It's quite striking in this case... the clear blue-green copper-loaded etchant turns a milky green, the precipitate settles out, and you're left with a clear near-colorless liquid which contains little or no copper.

I've heard of people disposing of copper-loaded used etchant by mixing in some Portland cement powder. This raises the pH, converts the copper to an insoluble form, and then binds it into (in effect) solid rock which can be disposed of in a landfill without causing significant leaching of copper. The same trick could no doubt be used to solidify the precipitated copper from a lye or soda-ash neutralization of spent etchant.

I get very good results with Staedtler Lumocolor film and
a HP 1200 dpi laser. The UV light source is a 500W halogen
floodlight.

3009. Identifying Surplus Toroid Material

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-28 22:12:37 UTC
From: skavanagh72nospam@yahoo.ca
Message-ID: <1148854357.331638.81030@y43g2000cwc.googlegroups.com>
Source record: 11911

I was rummaging around for a core for a small switching power supply and came across some 1.00" OD, 0.55" ID, 0.39" high (25x14x10 mm) toroids. A 50 turn coil measures about 1 mH (by measuring resonance at 200-500 kHz). This appears to indicate a permeability around 600, by comparing it with various catalogues. But the Q is rather low (equivalent series resistance is roughly 250 ohms at 500 kHz and 120 ohms at 200 kHz). Doesn't look likely to be good enough for a switching supply, so they may have to be relegated to EMI jobs (which I seem to recall they were used for in a piece of equipment I took apart).

But does anyone have any idea what material they might be ? Doesn't at first glance appear to be anything similar to what Fair-Rite makes. There's a good chance it is of Asian origin, I think.

73,
Steve VE3SMA

I've also heard of putting steel wool into spent ferric chloride etchant, which I think gets the copper out in a metallic form and probably replaces it with iron. Whether that would be better I don't know.

Since ferric chloride is another name for iron chloride, I'm not sure how that would work, since there is already an abundance of iron in the solution, but I've never tried it so I'm not going to say it won't work. However, I'd like to hear from somebody who HAS tried it, for better or for worse.

The 520 is a PEACH of a radio, however, you have discovered it's only short-coming. I tried to do something similar with mine years ago and gave up and accepted a weaker receive sensitivity on 15 and 10 Meters. Wish I could be of more help. Do you have the SERVICE manual for it? I believe I have one and will take a look and see if I can find any info for you...

Hello Jim

I use a similar setup to make boards all the time and it works reasonably well. No 8mil tracks tho. I just discovered some paper and haven't tried to see how small I can make the traces yet. I've been pretty sick for a few months and just haven't felt like messing with it. The one board I did make using it had much sharper defined edges and the drill guide holes etched nicely also with no residue left on the board. I never did find any photo paper that didn't leave the residue that needed cleaned off especially in the 25mil drill guide holes. The paper is made by Pulsar and is Digi-Key P/N 182-1003-ND. If you want to try it get the "GreenTRF" film to go with it, P/N 182-1021-ND. The GreenTRF film is just applied over the toner after it is transfered from the paper and leaves the image on the board completely sealed with a glossy green finish. I believe the paper was about $1 per 8.5x11 sheet and I don't remember how much the "GreenTRF" cost me, but it wasn't much for an 8in by 15ft piece.
I was making enough boards that I got myself a press designed for making T-shirts. Actually my wife got tired of me complaining about having to press so hard with the iron and bought it for me. It allows me to set the temperature and the clamping force precisely and repeatably, and it works great for transfering the image to the board. The press was kinda pricey, I think she paid about $300 for it. Now that's true love!
I've been using ammonium persulfate for etchant and just picked up some peroxide and acid so I can try making my own etchant.
I have a drill stand for my Dremel Moto-tool that was made by Dremel that I use for drilling the boards. I use a #10 Opti-Visor and have no trouble drilling the boards even with my pathetic eyesight. The etched drill guide holes in the center of the pads really helps hitting the holes dead center. With just a little care drills will last until they get dull. As a matter of fact the only time I break one is when I get careless trying to go too fast.
I'm feeling pretty good this afternoon, so I think I'll try making a board with a test pattern to see how fine I can get my tracks.

If I can run a track between 0.1" spaced pads and I'll be happy.
I think you'll like with your setup after you get the hang of doing
it.

Mike

Yes. Tracing paper/greaseproof paper seems distinctly better than clear
film. Bit queer, as I'd have thought the 'frosted-glass' finish would have
dispersed the UV light, much the same way as there still being daylight
after the sun has set. Maybe clear OHP film happily allows UV to bounce
around within the film thickness.

Last week did some quickie SOT23 to DIL adapters. Samsung ML-2250 laser,
600dpi. Single sheet. Very nice results.

15 mils is easy. 10 mils with some care. Below that, no promises.

The paper is made by Pulsar and is Digi-Key P/N 182-1003-ND. If

I use the glossy photo basic paper from Staples, or Costco, or Sam's Club,
or whatever branded private label -- it works better than the "premium"
variety photo paper for whatever reason. It all seems to work the same.
The trick is to use copper-brite scouring powder made specifically for
copper and brass along with one of those green dish scouring pads to clean
and microscratch the bejabbers out of the board before applying the resist.
It also helps to preheat the board for about 5 minutes at 150F in a toaster
oven after cleaning but before ironing on the resist.

> I've been using ammonium persulfate for etchant and just picked up

I've used ferric chloride, ammonium persulfate, and muriatic acid - hydrogen
peroxide and I MUCH prefer the muriatic-peroxide combination. What I have
NOT perfected in the etch process yet is a method of agitation for the
etchant. Right now I'm using an aquarium with an air pump and a "bubbling
stone", but would love to find another method. Perhaps I'll work on a
magnet with shrink sleeving and RTV to seal the ends and another magnet on a
motor underneath the aquarium bottom. That seems like a lot of hassle for a
simple agitation, but I haven't found a better way.

The school I teach for has a half dozen good PCB drills, so I'm not yet forced into that corner. I've also got a BIG pcb shop down the hill a bit, and they throw away carbide drills by the sackful. I've gotten them to throw a few sacks my way.

Be sure you really need to get that board out, I had an 820 that had the same symptom on 40m and the real problem was a dirty switch contact.

Also be sure to check all the solder joints and all the grounds, especially grounds via mounting hardware, that's not a young radio you have there.

Of course, if you've tried all that all I have to add is
Good luck!

Yeah, the persulfate is way too slow without a catalyst even when
heated and agitated, and ferric chloride is just too messy.

Is it really necessary to mix up the peroxide/acid for each session?
Could it be poured back into an airtight dark jug?

I too thought about the magnet stirrer. I just wonder if the magnets
would really setup any circulation in the tank.

The peroxide has oxidized to oxygen and water within half an hour after mixing, so all you really have is some diluted muriatic acid after each session. Besides, for $2 in chemistry, you can have an etched board.

I just rock the container continuously by hand in a larger container of
hot water. It only takes a few minutes.

I buy reground ones. They are a little shorter than new ones but that
doesn't matter for manual drilling and they are much cheaper.

Leon

You really did luck out. HBR-16'sw have been going for $300+ If the seller had known what he had, and advertised it correctly, he would have gotten twice as much.

Congratulations!

Looks like the company that put out the following PDF:

http://home.earthlink.net/~wksands/nonlin.pdf

has spice models. I suppose you have to pay for them, though. I'm surprised a Google search didn't turn up any free models. How accurate do they need to be? You can bulid your own, certainly...you can use the BJT model and add the package parasitic inductances, resistances, and capacitances, and probably get decent correspondence with the way real parts perform. I have a book about building Spice semiconductor models, but haven't done any of that for a long time and never was into it deeply enough to think I'm good at it.

www.duncanamps.com has quite a bit of spice stuff, including some transistor models and links (some broken by now) to manufacturers' spice stuff.

Cheers,
Tom

Herb,

I've also searched for the same Spice models and also any RF power transistor models. I didn't turn up anything except some very recent power devices with very very high (GHz) Ft. I was hoping to simulate a linear amplifier.

If you find anything please post again with details.

It's possible that I have confused myself and it might have been spent ammonium persulfate etchant instead, that the steel wool was to be put into. I don't enough about chemistry to say which would make more sense.

The one thing I have learnt about etchant is: Don't store ammonium persulfate etchant in a sealed (airtight) container. My bottle of etchant burst and went everywhere.

Chris

3032. New program. Dipole+Line+Balun+Tuner

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-05-31 00:09:35 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <hI2dnYwQvrs0feHZRVnyvg@bt.com>
Source record: 11933

New Program : LINELEN.exe

This program calculates dipole feedpoint impedance, transmission line
input impedance, and balun input impedance, versus frequency.

Dipole and line can be of any length. Line Zo can be of any
impedance.

Power lost in antenna and line is calculated. Also overall loss.

In addition to its educational value, this program will assist users
to change line length when the impedance presented to the tuner is
beyond its capability to transform it to a resistive 50 ohms.

Download self-contained program LINELEN, file size = 53 K-bytes, from
website below.

A bit more about spice models for RF transistors...

www.duncanamps.com has transistor models for some parts, as I noted before. Specifically, there are several models for Motorola RF parts, with the Moto numbers like MMBR931.

Some manufacturers provide spice models for current production parts, if not for obsolete ones. For example, if you download the Philips RF manual (as a PDF), you will find a page (current edition it's page 31) of links to parts with spice models. The links take you to the Philips page for that part; look for a link to the spice model on that page.

There seem to be some spice models on the ON semiconductor website, but I don't know how to search them very efficiently. Maybe there's a way...

Avago Technologies (used to be part of Agilent, used to be part of HP) generally has a good set of S-parameters for various bias conditions for their parts. Since the parts are generally intended for linear amplifier service, that's reasonable.

It would be nice to have a place on the web to archive at least links to models, if not (for copyright reasons) the models themselves. Anyone know of such a site?

Herb:

Take a look at http://www.sss-mag.com/pdf/rfosc.pdf and you'll find a 2N5109 SPICE model in the article.

Sorry, I don't have a 2N5179 model. Since there was a 5109 model, maybe enough patience will get you a model on Google.

Chuck

Steve, the usual reason for the apparent low Q is that it is not being measured at the frequency that will give highest Q. Try fewer turns and higher frequencies as a first attempt. I've measured many cores this way. If you like, I can email you an XL spreadsheet with the all the cores I've measured so far. Switchmode cores seems to have permeabilities quite a bit higher than 600.

Zetex has one, they make the 2N5179 in SMT (FFMT5179). I've got it in
my library, with two for other manufacturers.

Thanks chuck - what a beautifully designed website, will certainly book mark it for future reference.

Alas, its not germane to the TS520 - which has the coils and switches on the bottom of the PCB. The switch mechanism is lonber than the chassis, so it cant be pulled up vertically.

The only way I can see of doing it (and, hopefully, the Radio Pixies will come into my workshop over night so I dont HAVE to) is :-

1.Dont touch anything above the chassis line. Its a pig to re-align the chain drive on the 3 tuning capacitors. Turn radio upside down, make sure telephone is switched off and guard dog primed.
2.Remove metal shields between PCB coil/switch assemblies.
3.Not 100% sure this will work due clearance issues, BUT - undo 2 screws RHS outside chassis where the cage that is soldered to the RHS of the boards. Unsolder all the coils/pcb where they are soldered to the other side of the chassis rails. A big iron is needed for this - dont even THINK of doing it with your 40w temperature controlled esd safe for micro size things one....
4.Remove switch shaft by undoing coupling into pa cage. CAUTION - take notes, take pictures of wafer alignment for re-assembly. Its a PIG to redo from scratch....
5..Un wirewrap the 4 PCB's, vis the driver, antenna, mixer and oscillator boards. done from top. Not easy to see, but in a plane with the boards underneath.
6. Lift out whole switch/coil assembly - when there is enough clearance, undo the front facing wafer (the xtal oscillator board) and DO NOT lose any of the little weird size nuts, springwashers, and fibre washers. You can now put the front wafer to one side as it has heaps of wires soldered to it.
5.This SHOULD have the switch assembly free of the radio.If you have enough clearance on the RHS with the bracket still attatched, all is good. If you dont, then de-solder the RHS same as for the left.
5. Taking careful notes/drawings/photographs, dismantle the 2 rods each side of the band switch wafers, taking note of spacer positions.

To re-assemble - you can either solder the boards back in place AFTER you have mounted it back into the radio (be sure of physical alignment/clearances) or make up a simple wire wrap tool - if anyones interested, can email drawing. A slight pain to make up, but will make re-installing the boards electrically dead easy. And Murphys Law says you may (hah!) need to pull it out again.....
.....

You are now left with the coil and bandswitch pack for a 20 year old radio. Hopefully, some butcher hasnt been in there before you and totally wrecked it beyond repair.

73 de VK3BFA Andrew.

For etchant I find that CuCl2 and HCl work very nice -- and it is
especially advantagous to agitate by bubbling air thru the solution
since not only does it agitate but the oxygen in the air helps
regenerate the CuCl2 in situ. You can continue to bubble air thru it
after the etching is done to completely regenerate the etchant.

The reactions:
Etching: CuCl2 + Cu -> 2CuCl
Regenerating: 4(CuCl) + O2 + 4HCl -> 4(CuCl2) + 2(H2O)

Dr. G.

I appreciate the information but note that:

a. I cannot send my students/readers down to Home Depot to pick up a pound of copper chloride along with the muriatic (swimming pool grout etch) acid.

b. Now I've got a couple of gallons of etchant to keep around the lab in a proper container for the next go-around.

BTW, what is the color of the CuCl2 and the HCl mixed together?

Paying your electric bill adds money to the BPL bunch.

We must all withhold our electric bill payments until BPL is defeated.

A book I read a long time back recommended mixing spent solution with
concrete powder and sending the resulting brick to the dump. Seems like
one of the best ideas I have heard of if you really care about possible
impacts.

If you start off with HCl and H2O2, you get CuCl2. You don't need to
actually buy the stuff, it gradually becomes more concentrated with
use. Some form of chemical titration is needed with CuCl2 to ensure
that the concentration is correct and that it has the right pH.

Send them to HD to get some CuSO4.5H2O [Root killer Zep is one brand] and
some CaCl2 [Damp Rid (or in the winter: ice melter)]

Make a solution of each [equal molar amounts for each chemical] and mix.
Let it sit overnite. The white precipitate is CaSO4 [Plaster of Paris] and
the Blue-green solution on top is the CuCl2 solution. Best to filter that
to remove any remaining CaSO4. Now you have your starting supply of CuCl2
and as you can see from the equations you create more of it as you etch.
If you get too much offer it to another ham to get him/her started.

A very bright green. When it turns a dirty olive green you know it has too
much CuCl so start bubbling air thru until its bright green again.

A good library should have them. The British Library has held a copy of
everything published in the UK for a long time.

3053. Want To Build a Directional, Amplified Medium Wave Receiving Antenna - Where To Start?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-02 20:29:10 UTC
From: Dan Winker <dwinker@visi.com>
Message-ID: <12817sm5nfc9v3a@corp.supernews.com>
Source record: 11854

Hi all,

I'm not an amateur radio operator, but I do have the 1997 ARRL handbook, I am capable of understanding most of what it says, and this is definitely a question for a ham operator.

I live out in the country where the internet barely reaches and little radio stations are weak. My wife has recently taken to needing to listen to the ghost hunters show at 10 to midnight Sunday nights on KLBP which seems to me to be 5kW. It comes in acceptably during the day, but at night it's extremely weak and seems to be interfered with by another station. Maybe KLBP has to reduce their power at night. I don't know.

Now, instead of listening to the show Sunday night I can download the pod-cast Monday at work and give that to her. But if you're going to listen the the ghost hunting show, it seems much better to do it live, late at night, on an AM radio. Besides, that raises the possibility of calling in sometime.

A huge loop seems like overkill and not directional anyway. I don't think I have room for a dipole (is that 318 ft?). What I'm inventing in my own head is a loop with lots of turns. I think they used them in the old days. They were like a coil of wire mounted on a 2 ft by 3 ft board. Would (1005/1.47 = 684) feet of wire in a 3 ft diameter coil form some kind of ghost show antenna (for KLBP)?

I'm quite capable of reading parts of the ARRL handbook, ordering stuff from Digi-Key, and soldering. Where should I start? What about making it amplified?

BTW, here's my crystal radio that currently doesn't do anything because it doesn't have an antenna. http://www.visi.com/~dwinker/ddd_xtal_radio/ (It is finished now. I gotta get a final picture up now that I've posted this). It'd be cool if I could make that work again. I wouldn't feel to bad if it took an amplified antenna to make it work.

Thanks,
Dan

found this old Realistic Pro-45 "beast" of a scanner and it amazingly works.
it's an eight channel scanner that uses crystals.

currently a local 2-meter repeater is the only active frequency in my area.

can somebody help get or sell me some crystals and/or the manual for this
radio?

the crystals i'm looking for are:

148.525mhz
150.100mhz
154.935mhz
154.620mhz
156.800mhz
162.400mhz

please reply by email.

thanks!

The Realistic Pro-45 Patrolman Scanning Radio was introduced in 1978.

Strong Signals is a popular SWL / monitoring web site
http://www.strongsignals.net/index.cgi

First, start with the manual.
Anthony W. Haukap of St. Louis, MO has compiled Scanner Owners and Service
manuals:
http://myweb.accessus.net/~090/toc.html#scan

Here is his Radio Shack / Realistic series
http://myweb.accessus.net/~090/bearcatting.html#rsman

Photofacts from Howard Sams Publishing division of Prentice-Hall at
(800)428-7267, http://www.hwsams.com/sams_model_new.html

Repair Tips for Realistic Scanners (Bob Parnass, AJ9S)
http://www.repairfaq.org/REPAIR/F_RS_Repair.html

Crystals - they are not $2 each anymore !

ICM (they have deep library of equipment crystal specs - best in industry)

Dan:

If you want to buy something, take a look at http://www.ccrane.com/antennas/am-antennas/twin-coil-ferrite-am-antenna.aspx . This is a ferrite loop antenna which would seem to fill your bill. If you want something fancier, try Radios Plus at http://dxtools.com/ .

If you want to do it all yourself, my suggestion would be to check out the AM band clubs: the National Radio Club and the International Radio Club of America. Both have articles about constructing loop antennas of various styles.

Chuck

Dan,

You might read this area of my website:

http://www.w8ji.com/receiving.htm

If you have a weak staion with a strong co-channel staion causing problems, you need a directional antenna with a fairly wide and stable null. You won't find that in a single loop. You won't get much useful directivity or gain from any single element antenna, and a loop will be the same with 10 turns or one turn as long as you resonante it. It is the SIZE and balance that mainly affects sensitivity, pattern, or directivity.

Still, we can sometimes find a small antenna that just seems to work better than we might expect so experimenting doesn't hurt. But as a general rule you might have to use two elements phased to get a useful pattern

Wavelength of the wire is almost meaningless Dan.

684 feet of wire wound in a 3 foot diameter coil is still just a three foot diameter loop antenna.

It will have about the same pattern and same sensitivity as a single turn, assuming you can match and resonate each of them.

So you are really asking if a 3 foot diameter loop will work, and the only reliable answer is "maybe".

You can see from the Kanji in the transistor manual that the original
manufacturer is Hitachi (http://www.trexon.com/hitachi.gif)

..along with quite a few parameters. It's designed to be an RF power
amplifier, especially for CB.

This is supposed to be a similar part:
http://www.cpcares.com/pdf/2SC1817.PDF

with a similar (but less) power output rating (15W vs 18W for the
2SC2397 @27MHz output).

Best regards,

Gack! Well, you can bolt it in the same place and the pinout is the
same, but things kinda fall apart from there.. considering the ft of
the 3055 is 2MHz vs 100MHz for the 2SC2397.

** The Motorola " POWER Data Book" of 1982, lists the devices as "similar replacements" - as does the similar " Bipolar Power Transistor Data " of 1987.

I found at least 7 web sites, including the ST Microelectronics site, with the same info.

Seems some staffer at Motorola made an error in the early 80s and it has gone on and on and on ....

Thanks for the idea. Do you know how to contact the British Library? I guess I could search the internet.

I've had problems in the past. I can find a library that has the journal (usually in universities) but they all want you to go thru your local library to order a copy of an article. My local library doesn't want to try and get anything out of state.

Also libraries all want the page numbers and the title of the article and the author and I don't know that on these articles. That's why I was hoping to find someone who actually had the magazine.

Thanks
Bob

Maybe someone who was sick of the breaker-breaker-one-nine-rubber-duck
CB craze of the day? ;-) Unfortunately lots of references on the
'net may just mean that the stuff was all copied from one source.

BTW, any Japanese speakers here? The Japanese characters for Hitachi
appear to be only two syllables. The characters would be pronounced
"ri4 li4" in Chinese ('sun' or 'day' and 'stand'), maybe "hi ta" in
Japanese? Is the "chi" just tacked on in English?

Mazda is the opposite-- it's three syllables in Chinese (and probably
Japanese as well). And Alps (the component maker)is two syllables in
Japanese.

With Japanese Kanji, there's no telling. ;-) Fujiyama, for example,
is two Kanjis.

> Mazda is the opposite-- it's three syllables in Chinese (and probably

In Katagana or Hiragana, Ma zu da is three, yes, but A ru pu su is _four_! ;-)
(I think they're pronounced more like Ma z' da and A r' p' s'. :-))
To yo ta comes out just right, however. :-)

Cheers!

SolderSmoke #24: ROCKBOUND HB SSB, Two tone mp3, W1FB amp, SlimGem amp, ELSIE, Book review, Mailbag

SolderSmoke!
A SHOW FOR ELECTRONICS HOMEBREWERS!

http://www.ourmedia.org/node/231317

Topics discussed in SolderSmoke #24:

-- Mike's rockbound SSB success!
-- Two tone tests via mp3
-- W1FB 40 db amp strip
-- HF Packer SlimGem 5W MOSFET amps
-- ELSIE filter software
-- BOOK REVIEW: "From Crystal Sets to Sideband"
-- HF+6 diplexer
-- MAILBAG: Jerry AA6KI sends in "Lamp Talk" cartoon; Mike WA6ARA on VO-52 as a good QRP satellite.

NEXT EDITION: Bill will be using an Astatic D-104.

Listen at: http://www.ourmedia.org/node/231317

Background:
Tired of listening to Led Zepplin or NPR on your I-Pod? Wouldn't you like to be able to carry with you the kinds of ham radio conversations that you listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in London, England meet regularly on the ECHOLINK system to discuss their homebrew radio projects. We are making them available as PODCASTS.

NEW RSS FEED: You can subscribe to the program, have them downloaded to your MP-3 player, and listen to them at your convenience. To subscribe, just cut and paste this URL into your I-poder (or similar) software. We've been having trouble with our Ourmedia RSS feed, so Mike (software wizard that he is) has homebrewed his own RSS feed. In order to subscribe to SolderSmoke, point your podcast software to:

http://kl7r.ham-radio.ch/soldersmoke.rss

If you don't have an MP3 player you can just go to the site below and listen to the latest program (and earlier editions) using the audio software on your computer.

http://www.ourmedia.org/node/231317

Here's the homepage for our show. All our programs are available here. There is also a blog and links to some of the sites and documents we've been discussing: http://www.ourmedia.org/user/36170

We hope you enjoy the program. Please send us feedback.

Hi,

Working on converting an old CB to a 10 meter beacon. Obtained some xtals in the correct range I need, but they have 3 leads instead of 2. Are these resonators? Can I use them as direct replacement for xtals in the CB radio? Where does the 3rd lead go?

BTW, if anyone has a schematic for a barebones 10M tx, 1W +/-, please send a copy if you can with parts list.
Tnx!

Make sure to get a money back guarntee if it does not work for your
application. If you are to the east or west of the station you may be
fighting a loosing battle. The station may be shifting the antenna patern
north and south at night.

Do a search for 21.4 MHz filters. They have three leads and are used as
bandpass filters in UHF CB radios and may also turn up in 27MHz radios.
The middle lead probably goes to ground.

Andy writes:

Use an ohmeter to see if one of the leads is connected to the case
of the device. If it is, it certainly is a ground lead....
I have seen regular xtals with the third lead used as a case ground,
as well as xtal filters, which normally have a ground lead...

Actually I think such devices characterized for RF PA use are getting a bit thin on the ground with the CB craze over, most other HF applications needing more power and low-VHF most often using integrated modules or at least having the budget for real RF packages. But some comparison with other data sheets might be useful.

I actually have some (and a source for more at a good price, though production is not my intent) but was pondering if they could be stretched to 50 MHz, so the data sheets for similar devices may not be too applicable. Especially the MJE3055T !! I had noticed that curious substitution suggestion !

While I do not have a datasheet,
NTE quickcross has no equal,

here is some info for you (I'm not the author)

Many Asian-sourced semiconductors are marked per the
EIAJ standard
Electronic Industries Association of Japan,
which uses this code:

2Saxxxxb

2S -- a hint that it's not JEDEC

a -- the type of semiconductor, where
A = PNP bipolar
B = PNP bipolar
C = NPN bipolar
D = NPN bipolar
F = SCR
J = P-channel FET
K = N-channel FET
xxxx= 3- or 4-digit number

b = a suffix sometimes applied to designate updated
versions

Usually but not always,
if xxxx for 2A or 2B is under 500, or 2SC or
2SD is under 100, it's germanium;
else silicon for bipolars.

Leon:
I did find them and it looks real promising . They have the issue of Wireless World that I need. I will probably have to order a copy of the Table of Contents to see what page the article is on. Looks like a good resource. Thanks a lot.

You missed ft = 50 MHz.

Not like a 3055 at all.

I notice your 'advice' seems to be regularly flawed. I suggest you take more care.

Graham

3092. Matching to Crystal Filter

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-05 02:05:00 UTC
From: David <dhuisman@bigpond.net.au>
Message-ID: <gjMgg.3463$ap3.1904@news-server.bigpond.net.au>
Source record: 11893

Hi,

I am wanting to match the output of a SA602 Mixer to a 45MHz, 4-pole crystal filter and then match the output of the filter to the input of a SA605 IF receiver.

The filter datasheet specifies the termination impedance of 800 Ohms and 3pF.

I have not used crystal filters before and would appreciate some advice for typology of a suitable match.

The SA605 has a input impedance of 4500 Ohms par 3.5pF. Apparently they have a "sweet spot" if matched to 800R.
The SA602 has output impedance of 1500 Ohm (not sure of capacitance).

From what I can see, if I placed a 1k resistor across the SA605 input, this would give me close to 800R//3pF but not max. transfer of signal.

Some of the confusion I have is what to do with the 3pF termination requirement. I am not sure if this means that I could match the resistive components using an "L" or "Tapped C match" and then add another 3pF to each side of the filter ???

Any help much appreciated

Regards

David

Really? What are you going to do with the other 90 watts? The TO-3
version is rated at 115 watts It isn't even close. Even the plastic
version is 90 watts

Andy writes:

You've generally got it right....
A xtal filter wants to see a particular input SOURCE resistance and
a particular LOAD resistance to develop the passband it was designed
for....

If your source has an output impedance of 4500 ohms, you would
want to transform it down to the 800 ohms specified. This can be
done in a transformer, but I usually do it with a split capacitor tank
circuit..... making the inductor the tuneable part.

If the load wants to "see" a capacitance, I usually use a 2-20pf trimmer , together with whatever else impedance transformation is available. Then I can tune the variable cap for the desired passband characterists... Note that both the input and the output are tuned in my technique....

If you don't have a sweep generator, you can just sweep the gen you have back and forth to see if there are any ripples in the passband.... Optimum is generally with the minimum ripples... So, first tune the input and output for max output... Then rock the generator to check for ripples... Often a very small adjustment in the tuning will minimize the ripples at that point...

It ain't rocket surgery, but if you try to use fixed components it ain't gonna happen, since you don't know your circuit strays....

My wife has recently taken to needing to listen to the ghost hunters show at 10 to midnight Sunday nights on KLBP which seems to me to be 5kW. It comes in acceptably during the day, but at night it's extremely weak and seems to be interfered with by another station. Maybe KLBP has to reduce their power at night. I don't know.

Nobody mentioned propagation. It's probably day/night changes in the
atmosphere that are making the main difference in reception. A station
fairly close that you recieve ok in the day can be less strong at night.
Also strong stations far away that you would never hear during the day
can come in really strong at night due to bouncing.

A directional antenna may help some, but there is no guarantee that you
can solve your reception problem.

3096. Re: Matching to Crystal Filter

Message-ID: <6DOgg.3511$ap3.1380@news-server.bigpond.net.au>
Source record: 11798

Andy,

Thanks for the information. So my matching circuit may look like....

Mixer Out(1k5) -> Series coupling cap(1n) -> Var L to ground -> C-Tap
across L -> Crystal Filter -> C-Tap -> var L across C-Tap -> Coupling
C(1n) -> SA605 Input (4500//3.5 pF)

C-Tap caps to ground are also tuneable.

I suppose the Q of the match would not need to be particularly high as
the selectivity is provided by the Crystal filter.

Regards

David

3098. Re: Diff between xtal with 3 leads vs. 2 leads?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-05 04:51:57 UTC
From: C <temp1@tomochka.com>
Message-ID: <1149483117.438265.297750@g10g2000cwb.googlegroups.com>
Source record: 11800

Allison,

You might be misunderstanding. I'm modifying a Midland 13-380 to
transmit in the 10 meter band for use as a CW beacon. The xtal is
9.4MHz to replace the transmit xtal per instructions here:
http://www.4sqrp.com/resource/10m_beacon/10m_beacon.htm

Should put the freq up in the 10M beacon portion of the band if I can
hook up the 3 leads correctly and if it is indeed a proper application
for the part.

Thanks!

- C

Alan, are the ferrite toroids used to filter the output of pc power
supplies or the ac input of microwave ovens useful for other applications?

Or is the ferrite material lossy like the small ferrite beads used for emi
reduction on wires?

Regards,

Mike Monett

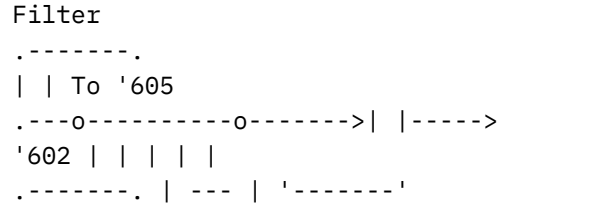
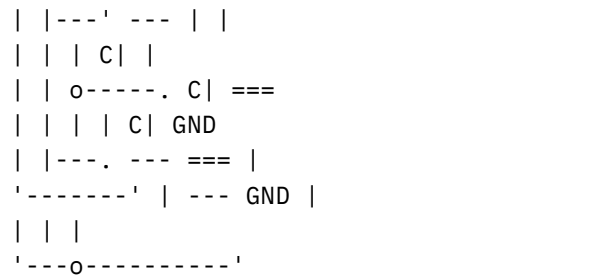
Something like this:





with an equivalent network going to the '605. You need enough Q to make the circuit appear balanced -- you're depending on the Q of the tank to overwhelm the inherent imbalance of the filter impedance. You _should_ be able to do this just by adjusting the coil, but I haven't tried it with crystal filters, so what do I know?

3104. Dissipating High RF Power in Vacuums

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-05 16:23:54 UTC
From: Bobby <originalbobjones@aim.com>
Message-ID: <1149524634.387224.292710@g10g2000cwb.googlegroups.com>
Source record: 11805

All,
What methods are commonly used to dissipate high RF power in vacuum chambers, apart from conduction cooled plates?

Any response is welcomed.

Thanks.

Bobby.

3105. Re: Diff between xtal with 3 leads vs. 2 leads?

Thanks Allison.

The Midland is of the second variety you described and will require retuing the sections once the TX xtal is replaced. Will take further questions off-line.

73,

C

Andy writes:

There is a formula for the required Q to perform the match.

Qreq'd = Square Root of ((Rhigh/Rlow) - 1)

1500
or Sqrt of (------------ - 1)
800

It's been a while so, if I got this wrong, I am sure some of the
local RF engineers will correct me...

Anyway,,, this is the minimum Q required in the tank to allow the
match
to be accomplished....

This comes from the equvalency formulae for series to parallel
comversion:

2 2
2
Rp = Rs (Q + 1) Xp = Xs (Q + 1) / Q

for coverting parallel resistance or reactance into equivalent
series resistance or reactance.....

Sure you can use Z and Y, but the above are much much easier.....

I can't follow your diagram very well, but I think you have it....
... I am assuming SINGLE ENDED OUTPUT. For balanced
output, it is different...

Before you try posting something like that again, you should make sure you are using a fixed-pitch font.

It probably is indecipherable to anyone except someone using the exact same proportional spaced font _and_ font size as you when you banged so many times on the space bar.

Andy,

Thanks. I am using single-ended output from the SA602 as well as for the
SA605 input. I decouple the unused output/input with 100n Cap in each case.

How do you know the match is working correctly ? My concern is that when
I build the circuit and sweep it with a sig gen and tune it for peak,
how do I know the match to is correct in the first place.

Regards

David

The PC PSU filter toroids seem to be optimized for the 25KHz -85KHz
range so any applications you have for this frequency range could use
them. Similarly, the AC input to the oven is probably 50/60HZ so those
toroids would be better at the lower audio frequencies.

> Or is the ferrite material lossy like the small ferrite beads used for emi
> reduction on wires?
>
Not quite sure about beads - ordinary ferrite material has fairly
constant permeability up to a frequency determined by the ferrite mix,
then drops off. Beads tend to have an impedance peak at some desired
frequency range - e.g. 100-200MHz

Andy replies:
Personally, I would use PSPICE to simulate the circuit to see if it
peaked
at the right point. Then I would measure the voltage at the top of the

tuned tank. Then I would replace the tank and load with a resistor
that
is equal to the source resistor and see that I have the same voltage...

Alternatively, the voltage on the output side of the Thevenin sourse
resistance should be half the voltage of the generator, if the load
is truly transformed up to the Thevenin source......

Little checks like that. Perhaps you can think of others..

I am sorry if your reader gave a problem with the formatting as I
was doing the best I could with what I had..... The "Qs" in the
last formulae are all " Q squared"..

You should look these formulae up in a book , like the ARRL handbook
or some other, to understand how they are used, and practice a little
with them... I wrote a BASIC program to do Series-Parallel conversion
using them, which makes it quicker (don't know where it is, tho).

Also, I would reccommend using PSPICE to verify all these small
circuits
to see how it works and verify that you are doing it right....
It's much easier that building and measuring, and you can try stuff out
and
get a better insight.....

Only if he has first-class laboratory facilities.

And samples vary widely in their characteristics, one from another.

The best way of using one is to wind some wire on it. If it works in
your particular circuit then consider yourself lucky.

It's not nearly as bad as Reg says, and a surprising response from someone who measures ground conductivity to great depths in a kitchen sink.

An antenna analyzer hardly qualifies as "first-class laboratory facilities", yet it can quickly show you the impedance and Q of an inductor wound on a core at any frequency within its range. If saturation with DC is a problem, the impedance can be measured while DC is passed through another winding from a source having a high impedance at RF. And samples of cores are typically alike in basic characteristics within a few percent.

Ferrites are more commonly used at RF for wideband transformers and EMI suppression than for high-Q inductors. In those applications, minimum impedance magnitude is usually the criterion rather than Q or having a precise value. So even a rough approximation of impedance is usually all that's required. The magnitude of impedance can be measured with a variety of simple means in addition to an antenna analyzer. Only in those applications where a high Q inductor is required, usually at low frequencies, are better measurements required.

Don't know what's common. Since it is a *chamber* you could "pipe" it out
of the chamber. Perhaps a water cooled jacket to a radiator on the outside,
or Peltier or heat pipe to a chamber wall.

Hello,

I'm searching a modification for the CB President Jackson to bring it
up to 30 Mhz.
I've searched on internet but I've only found simple modification to
add "F" band and reach 271 channels.
I'm a regularly licenced Ham!! and I want to use it on 30 Mhz.

Anyone know other modifications.

Thanks de Iw3arv Paolo Italy

The only other method is radiation, since you already mentioned conduction.

Many high power glass vacuum tubes are cooled primarily by infrared radiation. Tantalum or moly anode power grid tubes like the 4-400 or 3-500 are cooled primarily by infrared radiation and to a much lesser extent conduction out the metal element supports.

There is a coil.
It is 1" in diameter.
It is 2" long.
It has 20 turns.

How accurately can coil Q be determined at 30 MHz?

(1) Using an Autec antenna analyser?
(2) Using the best commercially available instrument.

Reg.

For RF matching and filter responses, I like to use RFSIMM99 which is an impedance analysis program using Sparameters.

The Sparameters are generally for active devices, but it also does a nice job with resistors, inductors, and capacitors. One trick it has is a tolerance analysis routine using monte carlo to choose randomg component tolerances. Very useful when testing to see if a particular circuit is likely to be tempermental, or if it will tolerate component variation.....

Just do a websearch for RFSIMM99 and you will find the program, it is freeware.

Love it!!
Actually, I measure Q by the following Method (for ferrite or iron
powder cores):
First, wind about 10 turns on the toroid. Then put a capacitor across it
- preferrably a 1% mica or similar. Now, connect to a signal generator
via a non-inductive resistor, put an oscilloscope (preferrably with a
X10 probe) across the parallel tuned circuit and find the resonant
frequency Fr. Add a smaller amount of capacitance across the circuit and
re-measure the Fr. Measure the signal generator voltage and the voltage
across the tuned circuit at resonance.
Now you have all the data necessary to calculate the inductance, stray
capacitance and Q. Vary the resistor so that the voltage drop across it
at resonance is about the same as the voltage across the tuned circuit
to maximise the measuement of Q.
If the Q is lower than expected, try a range of Fr by changing the
number of turns and/or the resonating capacitance.
How accurate is this? Good enough for my purposes :)

Those are good questions, although not particularly germane to the current discussion. A toroid is much easier to measure than an air core inductor with fair accuracy, since the field is largely confined. What makes solenoidal coils relatively difficult is the problem of avoiding coupling to the measuring device and nearby objects.

I'll mention again that ferrites are most commonly used at RF for wideband transformers, baluns, and EMI suppression. In those applications, Q is typically very low (1 or less) and generally immaterial.

To answer the question, though, I first note that your program predicts a Q of about 500 for this coil, with a Z of about 960 ohms and an ESR of about 1.4 ohms at 30 MHz. If it's correct, an antenna analyzer would be poor choice for measuring it for several reasons -- poor accuracy at that high an impedance, poor resolution of the ESR, and residual resistance in the measuring device. So probably +/- 50% would be wishful thinking. On the other hand, a good Q meter might make 20% if you could get the coil far enough away from the fixture, and I could probably do around 30% with my GR impedance bridge.

But what's the point you're trying to make?

Roy Lewallen, W7EL

3142. Re: Identifying Surplus Toroid Material

Newsgroup: rec.radio.amateur.homebrew

Source record: 11843

By the way, I found another surplus toroid with somewhat better characteristics....higher permeability and higher Q, as measured around 200 kHz. That has now been incorporated in a small switching power supply operating at about 30 kHz. It works, though not as well as is predicted by a SPICE model. Must be some of those vices that Reg mentions ! My SPICE model does not take into account the variation of the permeability/inductance with DC current, so this may be at least part of the difference. One of these years I'll break down and get an oscilloscope so I can figure out what non-microwave circuits are really doing, and maybe a signal generator that works below 150 kHz.

It is adequate (barely) for what I need, however, so it has now been incorporated as a bias supply in my 3.4 GHz transverter. I'm crossing my fingers that it keeps working over the temperature range it will encounter in portable operation.

The Q-measurement technique I have been using involves connecting a signal generator through a 50 ohm attenuator (to set the output impedance) to a 50-ohm input microwattmeter. The inductor and a capacitor are connected as a series-tuned resonant circuit and inserted either in series between the pad and the meter or shunted across the meter input. The inductance is obtained by finding the resonant frequency and working backward through the formula, given the known capacitance. The tuned circuit is then replaced with a resistor which is adjusted (by substitution) to give the same power on the meter as the tuned circuit at resonance. This resistance is equal to the equivalent series resistance of the tuned circuit, from which the Q can be determined.

As yet the Q results I obtain with the series and shunt connections tend to be somewhat different, so my techniques certainly have room for improvement (there are quite obvious stray-coupling issues, even at LF), but it gives me a rough idea, anyway.

3148. Modulated VXO + IF = HF FSK transmitter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-08 06:44:30 UTC
From: Ben Jackson <ben@ben.com>
Message-ID: <slrne8fhqe.23ns.ben@saturn.home.ben.com>
Source record: 11749

I've been brainstorming ways to make a cheap HF APRS beacon. HF APRS
is on 10.151, or more precisely, mark = 10.149.200 and space = 10.149.400.
It occured to me that if I had an appropriate crystal, FSK could be
a simple matter of driving two different voltages into a VXO. Of
course it's not easy to find a suitable crystal. I grabbed the list of
all crystals on Digikey and paired them up and sorted for the best
pairs producing mixer products near 10.149. The most promising combo
is 25MHz - 14.85MHz = 10.150MHz requiring 800Hz worst case pull to MARK
which is .006% of 14.85MHz.

So the idea is to use something like SA602A with the 25MHz LO and a
VXO driven by a microcontroller providing a ~14.85MHz "IF" with the
FSK signal (300 baud packet).

Has anyone tried something similar? I'm not sure if the VXO will
slew fast enough or accurately enough. I'm also wondering if a one-
time calibration of the VXO voltages would keep the output accurate
enough for a normal radio+TNC setup to consistently receive it.

Any ideas appreciated!

For 300 baud you should be all right -- I'm dinking with frequency-shift pulse position modulation with 1ms pulses, which work fine on a ~16MHz crystal.

I'd build it to adjust the 25MHz LO down a bit with some excessive capacitance in parallel, or with a coil in series. If you arrange for a trimmer in there someplace you won't have to play with adjusting voltages to the XCO -- in fact you could implement the XCO with a switching diode to a cap.

3150. 8875

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-08 18:29:36 UTC
From: Mitchell <mingram1234@alltel.net>
Message-ID: <aa250$44886c95$471c706c$28099@ALLTEL.NET>
Source record: 11751

Are there any replacement tubes available that are pin compatible with the 8875. I have the Dentron 2500.

Thanks,
Mitchell

3151. The doubly tuned circuit-key to clean hetrodyne or premix transmitters

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-08 22:52:19 UTC
From: WSQT <wsqtradio@ziplip.com>

Source record: 11752

One way of building a stable transmitter(in terms of frequency stability) is to mix the signal for a VFO operating at a relatively low frequency like 8MHZ or less with the signal from a crystal oscillator at VHF. This allows setting to any frequency and the use of FM without access to PLL chips.

The problem of course with this apporach is the tendency to radiate unwanted mixer products such as the image or the high oscillator signal. The mixer MUST be fed at least 10 db more high than low oscillator signal or harmonics of the low oscillator will leak out-almost always with one or more harmonics too close to the carrier to stop. Furtunately this is a mixer problem people long learned to minimize by limiting the level of the signal whose harmonics must be stopped.

The use of a balanced mixer can shut up the high oscillator leakage, but no mixer can in itself stop harmonics of the oscillator from beating with harmonics of the high oscillator. In addition, if your crystals won't oscillate on the 7th or 9th overtone and you have to use a multiplier its unwanted harmonics can leak. You can stop even harmonics with a push-pull multiplier, or odd ones witha push push(input in push-pull, output in parallel) multiplier, but some always wants to leak.

How do you solve this? THE SAME WAY OLD TUBE RADIOS GET I.F. SELECTIVITY-the doubly tuned, critically-coupled circuit. This is MUCH simpler to build than you might think.
It consists of two tuned circuits, inductively coupled to each other. Due to a detuning effect when overcoupled, it is necessary to reduce the coupling between them to the amount that just transfers full energy from the primary to the secondary. In my experience with transistor circuits, coils placed side by side and just touching work well.

Coils should have no more than 3 or 4 turns in the VHF range, and you can squeeze or spread the turns to get exact resonance, or change caps to if its really off. You tap the secondary coil at one turn for a match to a bipolar, or couple a FET to the top of the secondary coil. No trimmers or slugs needed, though if you don't mind buying a sack of trimmers they make alignment easier at the price of additional board space. Still, if I used trimmers for every circuit on one of my Gen X exciter boards, there would be more than 10 on the board and it would be much larger.

To align: first resonate the primary with the secondary disconnected. Then connect the secondary cap and resonate teh secondary coil. Now push the secondary further from and closer to the primary until you

find the point that just barely couples full energye into the secondary, checking resonance at each step.

Three or four transister amps including the mixer output stage with this arrangement will cut in-close spurs to such a low level that they will barely move the s-meter on a receiver 15 feet from an antenna energized with 60 watts of transmitter output power onb the carrier frequency.

3153. Re: Identifying Surplus Toroid Material

Newsgroup: rec.radio.amateur.homebrew
Date: 2006-06-09 09:52:25 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <128ih6tr5d8np4c@corp.supernews.com>
Source record: 11754

A couple of people have mentioned how they do inductor Q measurement. Here's how I do it:

I make a parallel tuned circuit with the inductor and an air variable capacitor. I've found that even mica capacitors often have a low enough Q to affect the measurement of reasonable Q inductors. The variable C also lets me do the measurement at the frequency of interest. I couple into and out of the parallel circuit with 1 pF capacitors, connecting one to a signal generator and the other to a 50 ohm termination and a scope. (If you calculate the parallel equivalent of the coupling cap and terminating resistor, you'll find that you need either a low or very high value of termination to avoid affecting the measurement.)

I've now got a signal generator with a digital frequency readout, but I used to use an old high level generator which I tapped into in order to hook up a frequency counter. I peak the scope signal at the frequency of interest. Then I vary the frequency slightly and find the precise center frequency and the -3 dB frequencies. The Q is simply the center frequency divided by the 3 dB bandwidth. For ease in making measurements, I built a simple 3 dB switchable attenuator and put it in line with the signal generator, terminating the output in 50 ohms at the Q meter so the attenuator would work properly. I measure the center frequency with the attenuator in, then switch it out and find the -3 dB frequencies by adjusting the frequency for the same output level as before. If you use the attenuator, the detector doesn't have to be linear, so you could do away with the scope and use just about any kind of detector like a diode and DVM.

Using this method I get within about 10% of an HP Q meter at HF, at least up to a Q of 300 or so, which is about the best I usually get with a powdered iron toroid core.

Im trying to lookup schematics/info the FCCs website:

https://gullfoss2.fcc.gov/prod/oet/cf/eas/reports/GenericSearch.cfm

I have the website but havent had much luck looking anything up using
fcc id #, sense this
is my first attempt then maybe theirs something im doing wrong on the
search page. Alot
of people seem to use the site for schematics and other good
information, seems like
it would great for the ham/experimenter. Any help getting started at
looking up information
on the fcc website would be appreciated.

I don't believe there is a direct replacement. There is / was, on the web, a mod to use another less expensive 4CX400A. It was writen by Bob Alper, W6KT in 1996. It replaces the tube sockets

Seems do be dead now:
http://www.svetlana.com/docs/TechBulletins/technoteNo14.html

Goran, SM2YER, lists other mods, but the links were too slow to respond for me to look at them.
http://support2.overkalix.se/~sm2yer/shack/amp_mla2500/

Ahhhh! Here it is from a Google search 6/9/2006: T R U S T G O O G L E ! !

http://dk9ip.ba-karlsruhe.de/pdf/mla2500/technoteNo14.html

Do a search on "Dentron MLA2500 Alper". Maybe it's still somewhere. I have a soft copy. Here's an excerpt:

The major problem for MLA-2500 owners is that there is no economical source for the 8875 tubes used as the active amplifiers. For under $350 including sockets and tubes, the amplifier can be converted to run two Svetlana Electron Devices, Inc. 4CX400A tetrodes. (The price of a Svetlana 4CX400A is $140.) .
In performing the conversion, five specific needs must be addressed. These are:

- Modification of the final amplifier tube area.

- Adding a screen power supply.

- Meter switching board change.

- Adding a bias power supply.

- Installing the passive input grid circuit.

I hit transmit too soon.
Note that the FCC ID is entered in pieces, the first 3 characters in the
first block, and all of the rest in the second block. That is all that you
have to enter. Try PY3WG511-F as an example. There are lots of
documents available.

Source record: 11760

Hello-
I recently acquired an AVCOM PSA 65A spectrum analyzer. I knew it was nonfunctional when I bought it, intending to repair it, but I'm amazed at how difficult it has been to find schematics for it.

An AVCOM rep sent me a PDF of the manual, but was unable to supply schematics. A google search of some of the prominent manual resellers didn't turn anything up. I have posted to a couple of Yahoo groups with no luck.

I thought there might be a homebrewer out there who uses one of these instruments and might be willing to share schematics.

Please reply to hpf (atsign) gainbroadband (dot) com

TIA

Neither of those should be a problem. The absolute level isn't important, and the amount you have to adjust the frequency for a single measurement is small -- for inductors of reasonable Q, anyway -- so the level probably won't change much over that small range unless the level stability is extraordinarily bad.

I've got a one-FET homebrew oscillator I made a long time ago with an extra transistor or two for a crude ALC that keeps it reasonably flat over the whole HF range. But you shouldn't need an ALC for most Q measurements.

One of the most frequent questions I receive is concerning the deterioration of the white silicon or vinyl cords on the older Weller TCP series soldering irons.

Weller does sell part number TC217, which is a black replacement cord with 3 pin plug already installed.
This is a good solution for the irons that have the Lightweight Nylon handle with black heater insulator/plug-in (after 1977) and mate to the WTCPN and later stations.

However, this is an expensive solution for the earlier TCP irons that had a phenolic handle/finger heat shield, such as the WTCPK (military set with 4-pin Jones plug) or W-TCP and WTCPL stations.

For these units, you have to cut off the 3-pin plug (expensive part of the assembly) from the replacement cord to wire the Jones plug or directly wire to the TCP base unit.

The phenolic handle irons used a metal ground strap that also serves as the cord's clamp and strain relief.
Removal and replacement of the old cord from this metal ground strap is difficult (and can be dangerous without proper tools)

Some restorers have used silicon or fiberglass/silicon sleeving or silicon tubing to build a new cord by removing the old vinyl or broken silicon insulation.

Another option is to use a replacement silicon cord from Rapid electronics (UK), order code 85-0590
which sells for 3.88 British pounds - considerably cheaper. This cable is not appropriate for the lightweight nylon handle, since it is slightly larger in outside diameter and uses the next high wire gauge 20 AWG .. instead of the original 22 AWG used by Weller.

Rapid order code 85-0590 Silicone, heat-resistant cable for soldering irons.

a.. Especially recommended for use with mains powered irons.
b.. Ideal for educational applications.
c.. Survives contact with a heated soldering iron tip.
d.. Convert existing PVC cabled irons to safer silicone cable.
e.. Pre-stripped and tinned.
f.. Overall length 1.5 metres.
g.. Suitable for use with all irons using 3-cored flexible cable.

Do you have any tips on fixing a Weller EC-2002-A? It still regulates
and heats, but the temperature display is dead. When first turned on it
flashes "FFF" for a split second. I think maybe bad filter capacitor or
something. Any thoughts on fixing? This is a nice unit I had just bought
spare iron and tips for it. Tried another iron, and also measured proper
resistance on the thermistor.

Unfortunately when I tried to order the Wireless World issue, it had already been sold.

Make sure you are clicking the correct hyperlink. The FCC pages are
weird. Also it could be that the manufacturer excercised secrecy in what
is allowed to be shown. I also notced a number of products have been
certified and later undergone major changes not reflected on the
database as having a permissable change.

CooperTools / Weller produced the "EC" (Electronic Control series for about 25 years (~ 1977 - 2002).
The series was discontinued the fall of 2002.

During that time they had a least 3 different revisions (and many more of control boards)

The original control boards were made on a ceramic substrate (yes it can and does crack). From the documents I have - the temperature board actually just serves as a calibrated reading from the sensor.

You may wish to look at eBay auction Item number: 7626510781 by ra2112. This is board 210 .. may be right board for you (not positive). These are (very rare) NOS repair control boards from a distributor close-out in southwest Chicago
(I have an old 1002 series 1 station running with a board from him).

Last resort is to call Dino Chandler, service manager at Weller - in North Carolina and see if they have any spare parts left to repair.

Greg
"**THE-RFI-EMI-GUY**" <rhyolite@nettally.com> wrote in message news:F8Lig.10221$Ui7.8851@tornado.tampabay.rr.com...
Do you have any tips on fixing a Weller EC-2002-A? It still regulates and heats, but the temperature display is dead. When first turned on it flashes "FFF" for a split second. I think maybe bad filter capacitor or something. Any thoughts on fixing? This is a nice unit I had just bought spare iron and tips for it. Tried another iron, and also measured proper resistance on the thermistor.

g. beat <@ wrote:
One of the most frequent questions I receive is concerning the deterioration of the white silicon or vinyl cords on the older Weller TCP series soldering irons.

Weller does sell part number TC217, which is a black replacement cord with 3 pin plug already installed.
This is a good solution for the irons that have the Lightweight Nylon handle with black heater insulator/plug-in (after 1977) and mate to the WTCPN and later stations.

However, this is an expensive solution for the earlier TCP irons that had a phenolic handle/finger heat shield, such as the WTCPK (military set with 4-pin Jones plug) or W-TCP and WTCPL stations.

For these units, you have to cut off the 3-pin plug (expensive part of the assembly) from the replacement cord to wire the Jones plug or directly wire to the TCP base unit.

The phenolic handle irons used a metal ground strap that also serves as the cord's clamp and strain relief.
Removal and replacement of the old cord from this metal ground strap is difficult (and can be dangerous without proper tools)

Some restorers have used silicon or fiberglass/silicon sleeving or silicon tubing to build a new cord by removing the old vinyl or broken silicon insulation.

Another option is to use a replacement silicon cord from Rapid electronics (UK), order code 85-0590
which sells for 3.88 British pounds - considerably cheaper. This cable is not appropriate for the lightweight nylon handle, since it is slightly larger in outside diameter and uses the next high wire gauge 20 AWG .. instead of the original 22 AWG used by Weller.

Rapid order code 85-0590 Silicone, heat-resistant cable for soldering irons.

a.. Especially recommended for use with mains powered irons.
b.. Ideal for educational applications.
c.. Survives contact with a heated soldering iron tip.
d.. Convert existing PVC cabled irons to safer silicone cable.
e.. Pre-stripped and tinned.
f.. Overall length 1.5 metres.
g.. Suitable for use with all irons using 3-cored flexible cable.

BE VERY CAREFUL ON USING REPLACEMENT IRONS (EC-1201 series) ON THE EARLY "EC" SERIES MODEL BASE UNITS

WELLER CHANGED THE PIN OUTS OF THE 5-pin CONNECTOR FOR THE IRON AND BASES WITH THE EC SERIES !!
THEY ARE DIFFERENT (EC-1201 is different from EC-1201-A and EC1201 P ... etc.) !!!

THIS CAN DAMAGE CONTROL BOARDS OR IRONS !!

SolderSmoke!
A SHOW FOR ELECTRONICS HOMEBREWERS!

http://www.ourmedia.org/node/235576

Topics discussed in SolderSmoke #25:

-- Bill puts Astatic D-104 on ECHOLINK
-- Mike's 80 mtr DSB rig becomes transceiver!
-- Mike's two chip EMRFD NE602-LM386 receiver
-- The rewards of homebrewing

NEXT EDITION: RECORDINGS OF MIKE and BILL's DSB
RECEIVERS!

Listen at: http://www.ourmedia.org/node/235576

Background:
Tired of listening to Led Zepplin or NPR on your
I-Pod? Wouldn't you like to be able to carry with
you the kinds of ham radio conversations that you
listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in
London, England meet regularly on the ECHOLINK system
to discuss their homebrew radio projects. We are
making them available as PODCASTS.

NEW RSS FEED: You can subscribe to the program, have
them downloaded to your MP-3 player, and listen to
them at your convenience. To subscribe, just cut and
paste this URL into your I-poder (or similar)
software. We've been having trouble with our Ourmedia
RSS feed, so Mike (software wizard that he is) has
homebrewed his own RSS feed. In order to subscribe to
SolderSmoke, point your podcast software to:

http://kl7r.ham-radio.ch/soldersmoke.rss

If you don't have an MP3 player you can just go to the

I bet if you had to send all this cw, you'd have trimmed the 300+
lines of useless crap you included.

John,

Are you using them in a series resonant circuit or parallel ?

Have you tried an inductor in series with the crystal (say 500nH to 800nH) ?

Regards

David

Overtone crystals do not oscillate at the _accurate_ integer multiple
of the fundamental frequency due to end effects.

Have you tried to run the crystal in the fundamental mode ? If the
produced frequency is close enough to 14.84833.. MHz, just put a
separate tripler after the oscillator.

>I have read that overtone crystals are hard to pull.

The pulling range is proportional to 1/Nï¿½ and since the needed pulling
range would be 67 ppm and assuming 3rd overtone crystals, the
comparable pulling range for fundamental mode crystals would be 600
ppm, which indeed is quite a lot.

John,

Most overtone crystals are designed for operation on their series resonance. There is also a parallel resonance, usually a few khz higher than the series resonance. The fact that your oscillator is putting out a signal a few khz higher than the frequency marked on the crystal is a good indicator that you might be operating the crystal in the parallel mode.

You shouldn't have to resort to any 'tricks' like operating it in its fundamental mode & multiplying, or putting frequency 'pulling' components in the circuit. It should come very close to the marked frequency if you use the correct circuit.

Can you refer to a circuit that's similar to yours so we can look at it and recommend what might be wrong?

3179. Schematic for Low Capacitance Fet Buffer

Newsgroup: rec.radio.amateur.homebrew

Hi,

I am looking for a circuit for a low capacitance FET circuit to act as a Buffer/Amp for VHF signals (ie. to probe Oscillators etc). (Homebrew Active Probe).

I have searched quite a bit on www but cannot locate a suitable design.

Thanks in advance

Regards

David

I need a capacitance meter scheme to test just varicap and several diodes
,
has anyone link(s)?

Being as the Alaska HighWay runs through Alberta, British Columbia, the
Yukon and Alaska it is a simple matter to search google for repeaters in
those areas.

Try these to start:

http://www.rac.ca/opsinfo/repeater.htm#Repeater%20Listings%20for%20locations%20in%20Canada

One starting point might be a homebrew active-FET oscilloscope probe design shown by Robert Pease in "Troubleshooting Analog Circuits" (page 16).

As shown, it has a bandwidth of 90 MHz, slew rate of 300 V/usec, input Z of 10^11 ohms in parallel with 0.29 pF. Construction is "ugly" style, with components soldered together in midair to minimize parasitic capacitance to ground.
